Persistent organic pollutants have not been conclusively associated with length of gestation or with preterm birth. Chlordecone is an organochlorine pesticide that has been extensively used to control the banana root borer population in the French West Indies. Data from the Timoun Mother–Child Cohort Study conducted in Guadeloupe between 2004 and 2007 were used to examine the associations of chlordecone concentrations in maternal plasma with the length of gestation and the rate preterm birth in 818 pregnant women. Data were analyzed using multivariate linear regression for length of gestation and a Cox model for preterm birth. The median plasma chlordecone concentration was 0.39 μg/L (interquartile range, 0.18–0.83). No correlation was observed with plasma concentrations of p,p'-dichlorodiphenyl dichloroethene ($\rho = 0.017$) or polychlorinated biphenyl 153 ($\rho = -0.016$), the other main organochlorine compounds detected. A 1-log$_{10}$ increase in chlordecone concentration was associated with a decreased length of gestation ($-0.27$ weeks; 95% confidence interval: $-0.50, -0.03$) and an increased risk of preterm birth (60%; 95% confidence interval: 10, 130). These associations may result from the estrogen-like and progestin-like properties of chlordecone. These results are of public health relevance because of the prolonged persistence of chlordecone in the environment and the high background rate of preterm births in this population.

chlordecone; French West Indies; length of gestation; persistent organic pollutants; pesticides; preterm birth

Abbreviations: DDE, p,p'-dichlorodiphenyl dichloroethene; LOD, limit of detection.

Organochlorines are manmade chemicals that are persistent and are still present in the environment despite no longer being used. These chemicals are considered to pose a threat to human health, particularly during periods of increased sensitivity, such as gestation (1, 2). A number of studies have shown associations between maternal or cord blood concentrations of p,p'-dichlorodiphenyl dichloroethene (DDE), the main metabolite of dichlorodiphenyl trichloroethane, and decreased duration of gestation and/or increased risk of preterm birth. The largest study conducted to date included 2,380 children from an early pregnancy cohort set up in the United States in the 1960s, and it showed a dose-response relationship between the maternal blood concentration of DDE and preterm birth (3). More contemporary studies with fewer participants and lower DDE concentrations have had conflicting results: Some (4–6), but not all (7–9), showed associations between DDE exposure and adverse outcomes. Several of these studies investigated a number of other organochlorines simultaneously. Increased risks of preterm birth associated with hexachlorobenzene levels have been described in 2 studies (8, 10), and associations with hexachlorocyclohexane (mainly the β isomer) were described in 2 others (4, 8).

Chlordecone (kepone) is an organochlorine insecticide principally used for control of the banana root borer in Central and South America and the Caribbean, including Puerto Rico (11). It was initially manufactured in the United States, but production and use were banned there in 1976. Subsequently, it was produced in Brazil and intensively used in
banana fields in the French West Indies from 1981 to 1993. It
is highly persistent in the environment; there is no significant
biotic or abiotic degradation. Some soils in current and pre-
vious banana fields and some waterways are permanently pol-
luted (12, 13). Currently, human exposure to chlordecone in
the French West Indies results mainly from the consumption
of contaminated food, especially seafood, root vegetables,
and cucurbitaceae, as assessed by studies in the general pop-
ulation (14) and among pregnant women (15).

The toxicity of chlordecone to humans was discovered in
1975 after a poisoning episode in pesticide plant workers in
the industrial city of Hopewell, Virginia. Male workers
showed evidence of sustained toxicity involving the nervous
system, liver, and testes (16–18). Additional studies on ani-
mals revealed that pregestational or gestational exposure of
rats and mice to chlordecone affected embryo implantation
and both prenatal and postnatal development (19). The mech-
anism of the toxic action of chlordecone is not completely
understood. It has been suggested that its hormonal prop-
erties may be involved. Chlordecone is an endocrine disruptor
with estrogen-like and progestin-like characteristics both in
vitro and in vivo (20–24).

Experimental studies have documented the toxic effects of
chlordecone exposure during gestation in animals, but there has
been no epidemiologic study to determine whether chlordecone
has similar consequences in humans at environmentally
relevant exposure levels. The Timoun Mother–Child Cohort
Study was established to investigate the impact on pregnancy
and child development of prenatal exposure to the widespread
chlordecone pollution in the French West Indies. Here, we report
the relationships between maternal exposure to chlordecone and
both the length of gestation and the risk of preterm birth.

METHODS
Study population

The present study was conducted in Guadeloupe (part of
the French West Indies), an archipelago situated in the Carib-
bean Sea with a population of 450,000 inhabitants who are
mostly of African descent. From December 2004 to Decem-
ber 2007, there were 1,068 women enrolled in a prospective
epidemiologic mother-child cohort study. Women were en-
rolled during third-trimester check-up visits at public health
centers (University Hospital of Pointe-à-Pitre, General Hos-
pital of Basse-Terre, and antenatal care units). To be eligible,
participants had to have resided in Guadeloupe for more than
3 years. The proportion of refusal was approximately 7%, and
the most common reasons were refusal of the spouse, not
wishing to participate in the follow-up, and not wishing to
provide biological samples. The study was approved by the
Guadeloupean Ethics Committee for studies involving
human subjects, and detailed informed consent was obtained
from each woman.

At enrollment, the participants answered a standardized
questionnaire during a face-to-face interviews with trained
midwives. The questionnaire covered sociodemographic
characteristics, medical and obstetrical history, and lifestyle
factors. Alcohol consumption during pregnancy was ascer-
tained on 2 occasions: during the interview at enrollment
and after delivery. After delivery, the medical history of the
pregnancy and delivery information were collected from mid-
wives, pediatricians, and hospital medical records. Cases in-
volving multiple births (n = 29), terminations of pregnancy
for fetal abnormality (n = 2), and stillbirths (n = 4) were ex-
ccluded, resulting in a study sample of 1,033 singleton live
births. From these eligible cases, maternal blood samples
were obtained at delivery for 818 women.

Outcomes

Gestational age in weeks was estimated by the obstetri-
cians in charge of follow-up. It was based on the first day
of the last menstrual period and was confirmed or corrected
by ultrasound. Data were available for 97% of the pregnan-
cies. Preterm birth was defined as a birth before 37 completed
weeks of gestation (25). We distinguished between spontane-
ous and medically induced births, Induced births included all
cases of induced labor and of caesarean delivery before the
onset of labor. Elective induced labor was not practiced at
the delivery centers involved in this study.

Exposure assessment

Maternal blood samples were collected into spray-coated
dipotassium ethylenediaminetetraacetic acid tubes. After
centrifugation, plasma samples were stored at −20°C. Sam-
ples were identified using only a sample code. They were
transferred by airmail on dry ice to Liege, Belgium, for or-
ganochlorine and lipid analysis.

Determination of chlordecone was done by the Center for
Analytical and Research Technology at Liège University in
Belgium. The preparation of samples and the quantification
method have been previously described (26–28). Details are
provided in Web Appendix 1, available at http://aje.oxfordjournals.org/. The limit of detection (LOD) was set at 3 times
the background noise of the chromatogram and was thus
0.06 μg/L. Samples from a subgroup of 358 women who de-
ivered after 37 weeks of gestation and whose children were
enrolled for neurodevelopmental follow-up were also assayed
to assess DDE and polychlorinated biphenyl 153 levels (26).
The LODs for both compounds were 0.05 μg/L. Total choles-
terol and triglyceride concentrations in plasma were determined
using standard enzymatic procedures (DiaSys Diagnostic Sys-
tems GmbH, Holzheim, Germany), and total lipid concentra-
tions were calculated as described previously (29).

Data and statistical analysis

Exposure was defined according to the chlordecone con-
centration in maternal plasma (modeled on a weight basis)
and was categorized in quintiles. A decimal log-
transformed continuous exposure variable was also used. Mul-
tiple imputations were implemented to impute chlordecone
concentrations below the LOD. The likelihood method was
used (30) under the assumption that chlordecone is log-
normally distributed. Five data sets with imputed concentra-
tions below the LOD were generated. Modeling of associa-
tions with the length of gestation and the risk of preterm birth was
performed within each set, and the results were combined
using the Proc MIANALYZE procedure in SAS (SAS Institute, Inc., Cary, North Carolina) according to the methodology described by Rubin (31) and Little and Rubin (32). Because the LOD was below the first quintile of the distribution, the multiple imputation exclusively applied to analyses based on the chlordane concentration as a continuous predictor.

We collected information on socioeconomic and lifestyle characteristics, including maternal place of birth (French West Indies, other Caribbean islands, or Europe), enrollment site (university hospital (Pointe à Pitre), local hospital (Basse-Terre), or antenatal care units), age (<20, 20–24, 25–29, 30–34, or ≥35 years), years of education (<5, 5–12, or >12 years), smoking during pregnancy (yes or no), and alcohol consumption during pregnancy (yes, defined as at least 1 drink during preceding week or 1 binge drinking session during the previous 3 months reported at enrollment or after delivery, or no). We also collected information on marital status, which we then classified into 3 categories corresponding to family profiles common in the French West Indies: single, living with a partner, and single but living with family (an adult member of her family, typically mother, father, sister, or aunt). Medical and reproductive factors recorded included parity (defined as the number of previous viable pregnancies: 0, 1, or ≥2), number of prior preterm births

c Two-sided P value for differences between rates (χ² test).

d Guadeloupe and Martinique.

e Weight (kg)/height (m)².

Linear regression models were used to evaluate the relationship between chlordecone exposure and the length of gestation. The regression coefficient (β) represented a difference of 1 week in the length of gestation per chlordecone exposure category or per decimal log unit of the transformed plasma chlordecone concentration. To describe the shape of the dose-response relationship, we examined splines (restricted cubic spline functions with 3 knots at the quartiles of the distribution) using the SAS macro developed by Desquilbet and Mariotti (33). This approach allowed identification of the linear and/or nonlinear components of the relationship. Associations between maternal exposure and the risk of preterm birth were estimated by calculating a hazard ratio using a Cox model that accounted for the left truncation that is a possible consequence of inclusion of participants during late pregnancy (34).
Although many risk factors for preterm births have been clearly established, the potential link between chlordecone exposure and these risk factors has not been thoroughly studied; this is due in part to the very small number of studies of this exposure in humans. Using current knowledge on preterm birth risk factors and the relationship between chlordecone exposure and these factors (Web Table 1), we constructed a directed acyclic graph for preterm birth (Web Figure 1). History of preterm births was not considered as a confounder because it reflects an unmeasured degree of vulnerability and simultaneously may be a consequence of previous exposure (if any association exists); therefore, it appears as a collider. Our data provided no evidence of an association between parity and levels of chlordecone (Web Table 1). This is consistent with the pharmacokinetics of chlordecone: Unlike most other organochlorines, chlordecone is not significantly stored in fat tissues, and plasma levels are therefore not significantly affected by the lipid tissue redistribution that occurs during pregnancy and breastfeeding. The minimally sufficient set of adjustment variables based on the proposed directed acyclic graph included maternal enrollment site, place of birth, marital status, educational level, age, body mass index before pregnancy, and high blood pressure during pregnancy. We conducted sensitivity analyses that included additional adjustment of parity and analyses that included adjustment for gestational diabetes, as well as analyses in which we excluded blood pressure.

In the subgroup of 358 women in whom DDE and polychlorinated biphenyl 153 were measured, the Spearman’s rank correlations coefficient between chlordecone and DDE was 0.017 (P = 0.75), and that between chlordecone and polychlorinated biphenyl 153 was −0.016 (P = 0.76). Therefore, DDE and polychlorinated biphenyl 153 were not considered to be confounders.

Lipophilic molecule concentrations are routinely expressed on a per-unit serum lipid basis, but this approach is prone to bias (35). Furthermore, a substantial portion of the chlordecone in blood is associated with proteins (mainly albumin) and high-density lipoproteins (36), whereas most other organochlorine compounds are associated with low-density lipoproteins and very high-density lipoproteins; consequently, expressing the chlordecone concentration on a per-unit serum lipid basis may be misleading. Nevertheless, to account for the residual chlordecone fraction transported by lipids, we considered total lipids in the adjusted models.

We also considered a possible interaction between chlordecone exposure and the sex of the newborn in relation to length of gestation and the risk of preterm birth. All statistical analyses were performed using SAS, version 9.3.

RESULTS

Most of the women in our study were born on Caribbean islands (primarily the French West Indies) where most inhabitants are of African descent, and most were multiparous (Table 1). Approximately two thirds were enrolled into the study at the University Hospital, and approximately two fifths were overweight or obese before pregnancy. Very few women reported smoking (5.8%) or alcohol consumption (2.9%) during pregnancy. The mean duration of gestation was 38.3 weeks, and 14.1% of the children (n = 115) were born preterm. Among the preterm births, 55 (47.8%) were spontaneous preterm births and 59 (51.3%) were medically induced preterm births; for 1 woman, the type of preterm birth could not be traced. Gestational age at enrollment (mean, 27.2 weeks) did not differ between spontaneous and induced preterm births and term births. Rates of detection and concentrations of organochlorine compounds in the plasma of a subsample of the study population are presented in Table 2.

We studied the shape of the dose-response relationship using splines. It appeared that the shape of the curve presented a significant decreasing linear component (P = 0.03), with the nonlinear component not being significant (P = 0.39) (Web Figure 2).

Table 3 shows the results of linear regression analysis for maternal chlordecone levels in relation to length of gestation. In the adjusted model, there was a statistically significant shorter length of gestation and the 2 highest quintiles of exposure. When studying exposure as a continuous variable, we found that higher maternal chlordecone levels were statistically significantly associated with a shorter length of gestation in adjusted models.
When all births were considered, the adjusted hazard ratio of preterm birth appeared to be statistically significantly increased for the fourth (hazard ratio = 3.1, 95% confidence interval: 1.6, 6.0) and fifth (hazard ratio = 2.2, 95% confidence interval: 1.1, 4.5) quintiles (Table 4). Expressing exposure as a continuous variable led to maternal chlordecone levels being statistically significantly associated with a higher hazard ratio for preterm birth in the adjusted model. Similar associations were observed when the analyses were done according to the mode of onset of labor (Table 4).

The findings remained unchanged when parity or gestational diabetes was included in the full model (Web Table 2). However, the strength of the associations decreased when high blood pressure was excluded from the model (Web Table 2). Women with high blood pressure during pregnancy appeared to have lower chlordecone blood concentrations than did other women (Web Table 1).

Women for whom we were not able to measure chlordecone concentration (n = 215) were more often recruited in the local hospital of Basse-Terre, which is in the most contaminated area in Guadeloupe. They tended to have shorter lengths of gestation (38.0 weeks vs. 38.3 weeks; P = 0.04) and a higher prevalence of preterm births (19.1% vs. 14.1%; P = 0.07) than did women for whom blood samples were available. Sensitivity analyses imputing expected median values of chlordecone according to major determinants of chlordecone exposure had only small impact on risk estimates (Web Table 3). Despite the interaction between chlordecone exposure and the sex of the newborn not being statistically significant (P > 0.2) in relation to length of gestation and the risk of preterm birth, the stratified results suggest a higher level of association among girls than boys (Web Table 4).

**DISCUSSION**

We examined the association between levels of chlordecone in maternal plasma and the duration of pregnancy in a population of pregnant women in Guadeloupe. We observed that greater maternal exposure to chlordecone was associated with shorter gestation. In addition, higher levels of exposure were associated with an increased risk of preterm birth in a dose-response-type association for all preterm births and for all modes of labor.

The present epidemiologic study is one of the few in which the association between chlordecone at environmentally relevant exposure levels and human health was examined (27, 37, 38). Local soil pollution by chlordecone (20% of agricultural lands) caused by its use in banana plantations between 1973 and 1993 has led to the contamination of root and cucurbit vegetables and of livestock and poultry that graze on these contaminated areas; costal fish and seafood are also contaminated. These contaminated foodstuffs represent only a fraction of what is consumed in the French West Indies, but they explain the chronic contamination of the population. Regulatory measures to restrict commercialization of these products that exceed threshold limit values of contamination have been implemented to reduce human exposure, but these measures only apply to licensed farms and fishermen. Indeed, there is an extensive informal network of production, distribution, and sale of foodstuffs, as well as families and individuals who produce food for their own consumption. These chains of supply are not adequately controlled.

Chlordecone has not been measured in populations other than those in the French West Indies (27, 37, 38) and Hopewell, Virginia (16, 17). The poisoning episode that affected pesticide plant workers in Hopewell (most of whom were men) during the mid-1970s led to a very high exposure rate, resulting in blood concentrations 100 to 1,000 times greater than those currently observed in the population of the French West Indies. Chlordecone exposure was also measured in adult Hopewell residents during the mid-1970s, and the serum concentrations in subjects with detectable values (at that time the LOD was around 1.5 μg/L) was between 5–32 μg/L (16), a range similar to those currently observed in the population of the French West Indies.

The strengths of the present study include its prospective design, the evaluation of exposure based on determinations of the chlordecone concentration in maternal plasma, and the consideration of co-exposures to other organochlorine compounds (DDE and polychlorinated biphenyl 153). Single

* The covariates for which we adjusted were maternal age, place of birth, enrollment site, marital status, educational level, body mass index, high blood pressure during pregnancy, and total plasma lipid level (g/L). The analysis was conducted on 767 complete cases.
Determinations of plasma chlordecone concentration provide an accurate reflection of the load of this compound in the body (17, 39). Its half-life in blood is approximately 6 months (17), so a single measure at the end of pregnancy can be considered to be reasonably representative of exposure throughout the pregnancy.

Our study also has some limitations. The prevalence of preterm birth in our study population was 14.1%, consistent with the high rate of preterm births among populations of African descent irrespective of their geographic location (40, 41). Nevertheless, we may have overestimated this rate because recruitment was mainly at the University Hospital, and this favors inclusion of pregnant women at risk of preterm birth. This also explains the high proportion of induced preterm births compared with spontaneous preterm births. However, any such oversampling should not impair internal comparisons. Also, the models for linear and logistic regression were adjusted for site of enrollment. There were small differences in some population descriptors between the subgroups with and without plasma chlordecone determinations, but sensitivity analyses indicated that these missing data were only weakly associated with risk (Web Table 3). In our study population, high blood pressure during pregnancy is associated with lower chlordecone blood concentrations, and we have no immediate explanation for this finding. The mechanisms through which chlordecone may lower the risk of high blood pressure during pregnancy, the possible influence of high blood pressure on chlordecone concentration in blood, or the influence of unknown confounders in this association remain to be studied. Inclusion of high blood pressure during pregnancy as a variable in the adjusted model reinforces the association between chlordecone exposure and risk of preterm birth.

We are aware that estimates of gestational age based on first trimester ultrasound may be biased if environmental exposure affects early fetal growth (42), although in practice the consequences of this problem are generally limited (43). Moreover, toxicological studies in rats and mice have indicated that chlordecone exposure during gestation, at doses that do not cause maternal toxicity, was not associated with low fetal growth (44).

Parturition is triggered by the shortening and dilatation of the cervix associated with uterine contractions. Progesterone plays a key role in maintaining pregnancy. In humans,

a The covariates for which we adjusted were maternal age, place of birth, enrollment site, marital status, educational level, body mass index, high blood pressure during pregnancy, and total plasma lipid level (g/L). The analysis was conducted on 750 complete cases for all births, 694 spontaneous preterm births, and 703 induced preterm births.

b For one woman, the type of preterm birth was unknown.
progesterone-receptor-dependent events, rather than circulating progesterone levels, appear to be critical (45). For example, treatment of pregnant women with progesterone-receptor antagonists induces labor at any stage of pregnancy (46). Chlordecone binds estrogen receptors α and β, acting as an agonist of estrogen receptor α and an antagonist of estrogen receptor β (47, 48). It also stimulates the synthesis of the progesterone receptors in rat uterine tissues in vivo (21), and this process is mediated by estrogen receptors. Chlordecone can inhibit the binding of the progesterin agonist R5020 to the form A of the progesterone receptor in vitro (22). These observations suggest that the observed associations between exposure to chlordecone and both decreased gestational length and increased risk of preterm birth are due to the estrogenic and/or progesterin activities of chlordecone.

In summary, the data that we report provide some evidence that chlordecone, a chemical with well-established estrogen-like and progestin-like properties, may affect the duration of gestation (with gestation at least 3 days shorter for the 40% of women with blood chlordecone levels >0.52 µg/L) and thus increase the risk of preterm birth. These findings were observed in a population with a high baseline risk of preterm birth. The association was detectable even though the concentrations of chlordecone in the blood were in the order of magnitude of 1 part per billion. Further efforts are required to protect pregnant women against exposure to chlordecone, particularly from its major dietary sources.
