Abstract

In this article, we report a convenient and efficient method for the synthesis of new simplified derivatives of hemiasterlin in which the α,α -dimethylbenzylic moiety A is replaced by α,β -unsaturated aryl groups as Michael acceptor. Most of these derivatives have a strong cytotoxic activity on three human tumor cell lines (KB, Hep-G₂ and MCF₇). Analogs 17b and 17f showed a high cytotoxicity against KB and Hep-G₂ cancer cell lines comparable to paclitaxel and ellipticine.

Hemiasterlins belong to a family of naturally occurring tripeptides from marine sponges.¹ The important derivatives of hemiasterlins are hemiasterlin A, hemiasterlin B, and hemiasterlin C, which were isolated from marine sponge *Auletta* and *Cymbastella* (Fig. 1) and exhibited potent cytotoxicity *in vitro* against murine leukemia P388 and human breast, ovarian, colon, and lung cancer cell lines.^{2,3} Hemiasterlins suppress microtubule depolymerization presumably by binding to the vinca-alkaloid binding-domain of tubulin and leading to mitotic arrest and cell death.^{4a} The synthetic analog HTI-286 (**2**) displayed especially potent cytotoxicity against paclitaxel (TaxolTM) resistant tumor cell lines *in vitro* and *in vivo* and is currently in clinical trials.^{4b}

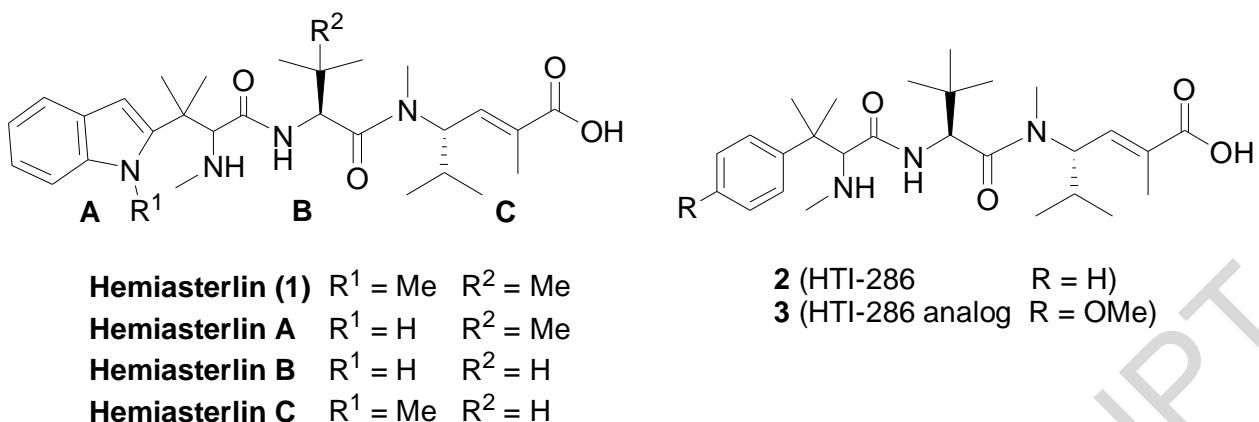

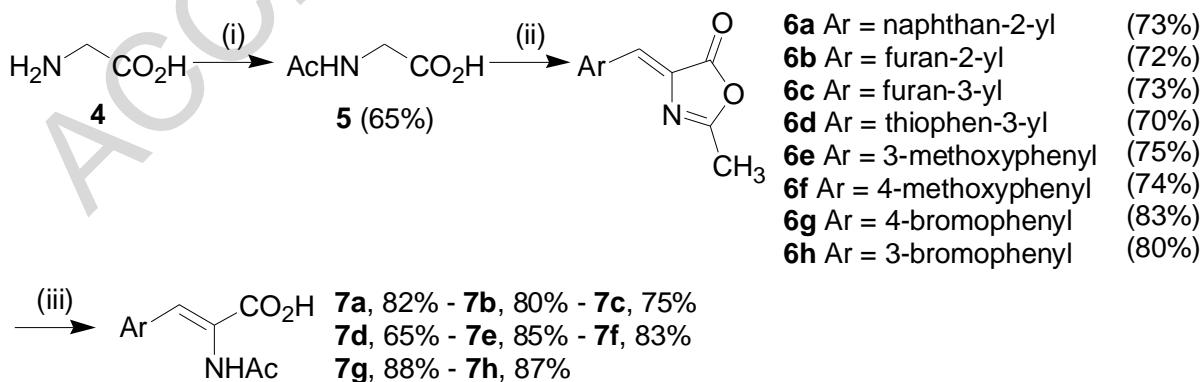

Figure 1. Structures of hemiasterlin derivatives and HTI analogs.

There are several reports on the synthesis of new derivatives of hemiasterlin in which the indole aromatic ring in the moiety **A** of the original molecule was replaced by aryl functional groups.^{5,6a} However, asymmetric synthesis of the stereospecific amine group and especially the *gem*-dimethyl moiety were proved to be highly problematic. To overcome this difficulty, several studies explored modifications of segment **A** in which the *gem*-dimethyl moiety has been eliminated. Some of these derivatives showed promising cytotoxic activity.

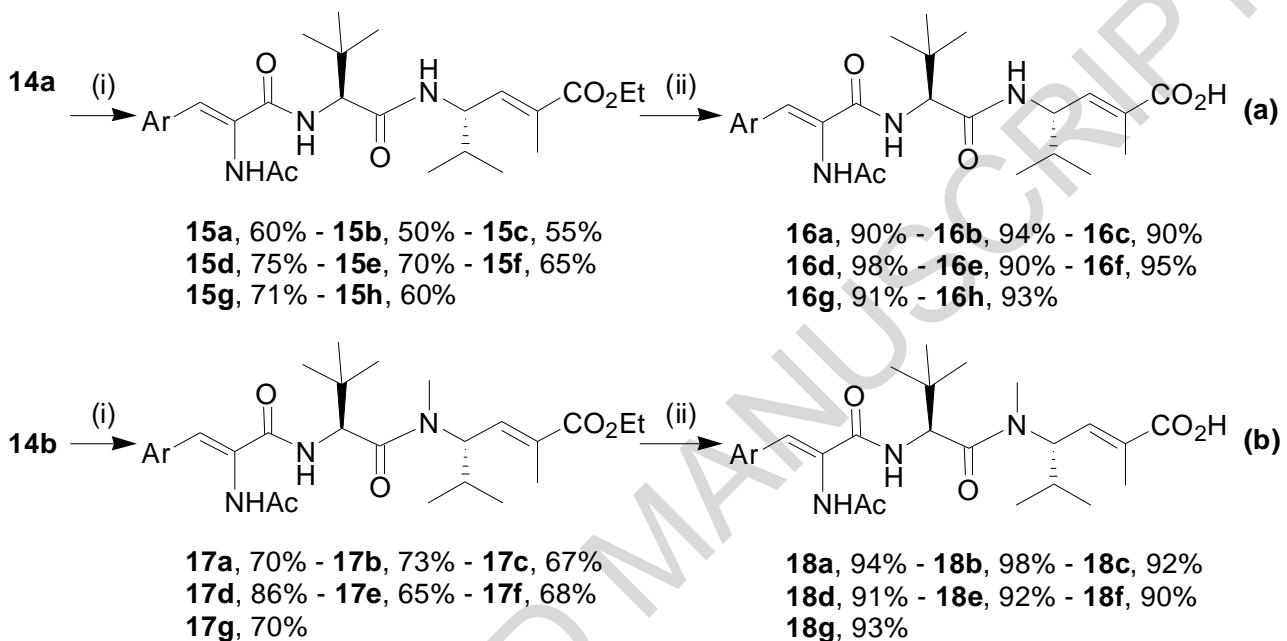

In recent years, previous works have shown that the presence of a α,β -unsaturated carbonyl system in peptide derivatives can improve the biological activity compared to the initial compound.^{7,8} Explanations may include either a limitation of free energy of the peptide by addition of a constrained system or by an electrophilic character of the compound leading to the possibility to form covalent bond with the protein target. Based on the idea that hemiasterlin derivatives containing α,β -unsaturated carbonyl systems could induce a remarkable cytotoxicity, we decided to synthesize new hemiasterlin derivatives in which the α,α -dimethylbenzylic group (fragment **A**) is replaced by a α,β -unsaturated carbonyl group.

New hemiasterlin derivatives were synthesized via classical peptide coupling reactions between two fragments **7a-h** and **14a,b**. A general procedure for the synthesis of compound **7** is outlined in Scheme 1. Compounds **7** were prepared from glycine in three steps.⁹ The synthesis started by acetylation of glycine with acetic anhydride in water at room temperature following by condensation with aryl aldehydes using sodium acetate in the presence of acetic anhydride at 90 °C for 12 h which afforded azalactones **6a-h** in 72-83% yields.⁹ Finally, azalactones **6a-h** were hydrolyzed in aqueous sodium hydroxide, followed by treatment with hydrochloric acid (12 N) at 100 °C for 4 h to give compounds **7a-h** in 65-88% yields.

Scheme 1. Reagents and conditions (i) 2.0 equiv Ac_2O , H_2O , rt, 20 h. (ii) 0.75 equiv ArCHO , 1.0 equiv AcONa , Ac_2O , 90 °C, 12 h. (iii) NaOH (1 N) then HCl (12 N), 100 °C, 4 h.

Compounds **14a,b** were obtained from Boc-L-valine in 6 steps as depicted in Scheme 2.⁴ In the first step, Boc-L-valines **8a,b** were converted to Weinreb amide **9a,b** in good yields (86 and 81%) by treatment with a mixture of *N,O*-dimethylhydroxylamine hydrochloride, 1-ethyl-3-(3-dimethylaminopropyl)carbodiimide (EDC) and hydroxybenzotriazole (HOBr) in the presence of N-ethylisopropylamine (*i*-PrNHEt) at room temperature for 12 h.¹⁰ Reduction of **9a,b** using LiAlH₄ in THF was carried out at room temperature for 1 h to give aldehydes **10a,b** in 78% and 65% yields, respectively.¹¹ Afterward, Wittig reaction of aldehydes **10a,b** with ethyl 2-(triphenylphosphoranylidene)propanoate was carried out at reflux in CH₂Cl₂ for 6 h to afford the alkenoates **11a** and **11b** in 86% and 88% yields, respectively.^{6,12} Then, removal of the Boc group using trifluoroacetic acid in CH₂Cl₂ at room temperature for 1 h led to **12a,b** in high yields (90 and 95%). The expected compounds **14a,b** are finally obtained after coupling **12a,b** and Boc-L-leucine in the presence of EDC/HOBr in DMF at room temperature for 12 h following by Boc deprotection in classical reaction conditions.

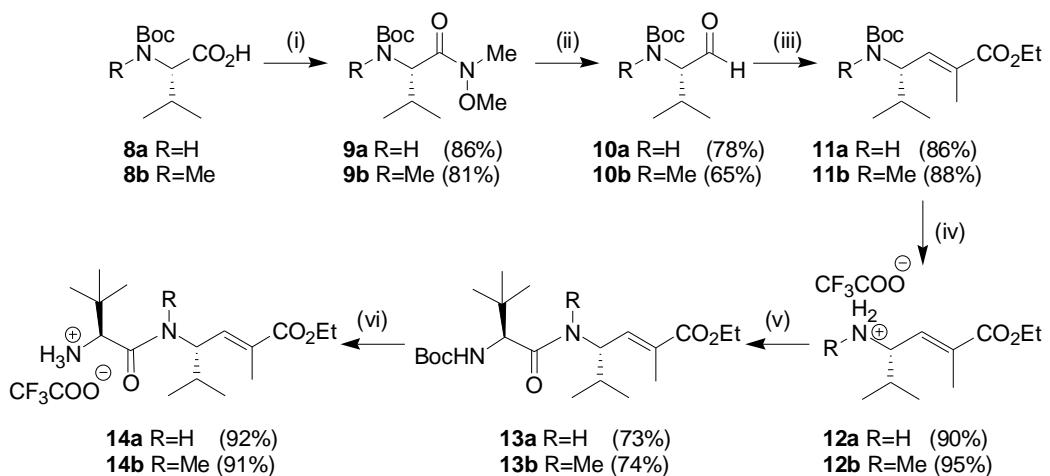

Scheme 2. Reagents and conditions (i) 1.1 equiv NH(Me)OMe.HCl, 1.1 equiv EDC, 1.1 equiv HOBr, 2.0 equiv *i*-PrNHEt, DMF, rt, 12 h. (ii) 4.0 equiv LAH, THF, rt, 1 h. (iii) Ph₃P=C(CH₃)CO₂Et, CH₂Cl₂, reflux, 6 h. (iv) TFA, CH₂Cl₂, rt, 1 h. (v) 1.0 equiv Boc-L-Leucine, 1.1 equiv EDC, 1.1 equiv HOBr, 2.0 equiv *i*-PrNHEt, DMF, rt, 12 h. (vi) TFA, CH₂Cl₂, rt, 1 h.

The final compounds **16a-h**, **17a-g** and **18a-g** were then prepared in two steps after peptide coupling reactions of **14a** with amides **7a-h** following by the saponification of ester using a 1 N lithium hydroxide solution (Scheme 3-a). Similarly, the hemiasterlin derivatives **18a-g** were obtained from **14b** (Scheme 3-b).

All compounds **15a-h**, **16a-h**, **17a-g** and **18a-g** were evaluated in vitro for their cytotoxic activity against four human tumor cell lines (KB, Hep-G₂, LU and MCF₇) and the results were summarized in Table 1.

Eleven hemiasterlin derivatives showed strong activity against the KB, Hep-G₂ cell line with IC₅₀ value below 100 nM. Analogs **16b**, **17b** and **18f** exhibited potent cytotoxicity against the KB cell line with IC₅₀ = 8.2, 3.5 and 3.7 nM, respectively. Meanwhile analogs **16b**, **2217c** and **17f** displayed potent cytotoxicity against the Hep-G₂ cell line with IC₅₀ value 17.8, 16.3 and 3.7 nM, respectively. Derivatives **15a**, **15e** and **17a** presented a cytotoxic activity against MCF₇ cell line with IC₅₀ value 42.3, 60.0 and 67.9 nM. Concerning the last cell line, the LU cell line, the hemiasterlin analogs showed weak activities with IC₅₀ values above 269 nM. It is noteworthy to mention that two derivatives **17a** and **17f** present a cytotoxic activity against two cancer cell lines (KB, Hep-G₂) comparable with those of ellipticine and paclitaxel.

Scheme 3. *Reagents and conditions* (i) 1.0 equiv **7a-h**, 1.1 equiv EDC, 1.1 equiv HOBT, 2.0 equiv *i*-PrNHEt, DMF, rt, 12 h. (ii) 10 equiv LiOH, MeOH : H₂O (2:1), rt, 10 h.

Table 1. Cytotoxicity evaluation.

31	Ellipticine	1.26	1.26	1.82	2.15
32	Paclitaxel	3.9	0.19	-	-

In conclusion, a concise synthetic approach for new modified hemiasterlin derivatives was achieved in which the α,α -dimethylbenzylic group and amino NHMe moiety were replaced respectively by a α,β -unsaturated aryl and an amide NH-Ac group avoiding the synthesis of the chiral fragment A. Most of these derivatives possess strong cytotoxic activity on three human tumor cell lines (KB, Hep-G₂ and MCF₇) and two analogs, **17b** and **17f**, showed a comparable cytotoxicity activity to paclitaxel and ellipticine against KB and Hep-G₂ cancer cell lines. Based on previously reported work,^{6b} we can envisage that our hemiasterlin derivatives act as tubulin polymerization inhibitors. From our best compounds, more detailed biological studies will be undertaken and will be reported in due course.
