

groups, such as a 2-benzylbenzoxazole, have been functionalised without catalyst.^{9b,9c}

As the methods for the construction of sp³-sp³ carbon-carbon bonds from unactivated sp³ C-H bonds of 2-alkylazoles remain scarce, the reactivity of such alkyl groups needed to be investigated. We now report conditions for the functionalization of a 2-ethyl substituent on a thiazole derivative with ethyl 2-bromomethylacrylate as the reaction partner, and show the scope of the sp³ functionalization of 2-alkyl-substituted thiazoles, imidazoles, oxazoles and pyridines.

Scheme 1 Reported examples of sp³ functionalization of 2-alkylazoles or 2-alkylpyridines.

2. Results and discussion

We initially compared the reaction of 2-ethyl-4-methylthiazole and ethyl 2-bromomethylacrylate with and without Pd-catalyst in DMA at 150 °C (Table 1). The presence of PdCl(C₃H₅)(dppb) complex in the reaction mixture had no influence both on yield and selectivity of this reaction (Table 1, entries 1 and 2). The use of such conditions resulted in the formation of mixtures of the target coupling products **1a** and **1b** in a 90:10 and 92:8 ratios, respectively. It should be noted that in both cases, no sp³ C-H bond functionalization at position C4-Me of the thiazole was observed. Lower selectivities in product **1a** were obtained using NMP and DMF as the solvents, in absence of palladium catalyst (Table 1, entries 3 and 4); whereas CPME, *o*-xylene, ethylbenzene and 1,4-dioxane were completely ineffective for this reaction (Table 1, entries 5-7, 9). No reaction also occurred in ethylbenzene or 1,4-dioxane in the presence of 1 mol% PdCl(C₃H₅)(dppb) (Table 1, entries 8 and 10). The nature of the carbonate cation has an important influence on this reaction, as both Cs₂CO₃ and Na₂CO₃ gave low yields of **1a** (Table 1, entries 11 and 12). The low yield obtained with Na₂CO₃ might be due to its poor solubility in DMA; whereas the higher basicity of Cs₂CO₃ might be harmful for the reaction.

Acetates are not suitable bases for this reaction due to the side reaction of acetate anion with ethyl 2-bromomethylacrylate which affords ethyl 2-(acetoxymethyl)acrylate (Table 1, entry 13). The relatively strong base NaOtBu in *o*-xylene, with or without palladium catalyst, was also ineffective (Table 1, entries 14 and 15). The use of 2.5 equiv. of 2-bromomethylacrylate allowed to obtain **1b** in 48% selectivity and in 33% yield (Table 1, entry 16). Finally, a lower reaction temperature of 110 °C affords **1a** in high selectivity but in very low yield (Table 1, entry 17).

Table 1. Influence of the reaction conditions for the coupling of 2-ethyl-4-methylthiazole with ethyl 2-bromomethylacrylate.

Entry	Base (equiv.)	Solvent	Ratio 1a:1b	Yield in 1a (%)
1	K ₂ CO ₃ (1.5)	DMA	92:8	80
2	K ₂ CO ₃ (1.5)	DMA	90:10	79 ^a
3	K ₂ CO ₃ (1.5)	DMF	76:24	nd
4	K ₂ CO ₃ (1.5)	NMP	87:13	61
5	K ₂ CO ₃ (1.5)	CPME ^b	-	0 ^c
6	K ₂ CO ₃ (1.5)	<i>o</i> -xylene	-	0 ^d
7	K ₂ CO ₃ (1.5)	ethylbenzene	-	0 ^d
8	K ₂ CO ₃ (1.5)	ethylbenzene	-	0 ^{a,d}
9	K ₂ CO ₃ (1.5)	1,4-dioxane	-	0 ^c
10	K ₂ CO ₃ (1.5)	1,4-dioxane	-	0 ^{a,c}

17	K ₂ CO ₃ (1.5)	DMA	97:3	<10 ^c

Conditions: 2-ethyl-4-methylthiazole (1.5 mmol), ethyl 2-bromomethylacrylate (1 mmol), under argon, 16 h, 150 °C, isolated yields. ^a 1 mol% PdCl(C₃H₅)(dppb). ^b CPME: cyclopentyl methyl ether. ^c 110 °C. ^d 130 °C. ^e 2-ethyl-4-methylthiazole (1 mmol), ethyl 2-bromomethylacrylate (2.5 mmol), K₂CO₃ (3 mmol).

The first step of the reaction is certainly the addition of the bromomethylacrylate to the nitrogen atom of the azole derivative to form the *N*-alkylated species **A** (Scheme 2). Deprotonation of **A** in the presence of K₂CO₃ affords intermediate **B**. Then, an aza-Cope rearrangement leads to the final product **a**.¹⁰⁻¹²

Scheme 2 Proposed mechanism

Using K₂CO₃ as base in DMA, (Table 1, entry 1), the scope of the sp³ C-H bond functionalization using various 2-alkylthiazole derivatives was examined (Scheme 3). From 1.5 equiv. of 2,4-dimethylthiazole and 1 equiv. of ethyl 2-bromomethylacrylate, a mixture of **2a** and **2b** was obtained in a 19:81 ratio. The use of a

larger excess of 2,4-dimethylthiazole (3 equiv.) did not allowed to obtain **2a** in good selectivity. Again, no sp^3 C-H bond functionalization at position C4-Me thiazole was observed. On the other hand, the reaction of 2-*i*-butylthiazole or 2-*i*-propylthiazole (1.5 equiv.) with ethyl 2-bromomethylacrylate (1 equiv.) led exclusively to mono-coupling products **3a** and **4a** in moderate to high yields. Then, we studied the influence of benzene substituents of 2-*i*-butyl-5-arylthiazoles for such couplings (Scheme 3). Nitro-, chloro- or cyano- substituents are tolerated to afford **5a**, **6a** and **8a** in 51-66% yields. The highest yield was obtained from 2-*i*-butyl-5-*p*-tolylthiazole to give **7a** in 77% yield.

Scheme 3 Scope of the sp^3 functionalization of 2-alkylthiazoles.^{13,14}

We then studied the reactivity of a set of 2-alkylheteroarenes which do not contain a nitrogen atom at 3-position with and without $PdCl_2(C_3H_5)_2(dppb)$ catalyst (Scheme 4). As expected, both 2-methylthiophene and 2-*n*-butylfuran gave no trace of coupling products **9a** and **10a**. The reactions in the presence of 1,2,5-trimethylpyrrole and 2,4-dimethylisoxazole were also unsuccessful as **11a** and **12a** were not detected by GC/MS analysis of the crude mixtures. The reaction of 2-ethyl-4-methylthiazole with allyl bromide or allyl acetate in order to produce **13a** was also unsuccessful (Scheme 4, bottom).

Scheme 4 Limitations of the sp^3 functionalization of 2-alkylheteroarenes.^{13,14}

The influence of the nature of the heteroatom at position 1 of the heteroarene was also examined (Scheme 5). The reaction of 1.5 equiv. of 1,2-dimethylimidazole with 1 equiv. of ethyl 2-bromomethylacrylate only gave mono-coupling product **14a** in 71% yield. Similarly, 1-benzyl-2-methylimidazole only afforded

the mono-coupling product **15a** in 65% yield. On the other hand, a mixture was obtained from 1-decyl-2-methylimidazole with the formation of **16a** and **16b** in a 82:18 ratio. However, the use of a larger excess of 1-decyl-2-methylimidazole gave **16a** in 99% selectivity and 78% yield. From both 2,4,5-trimethyloxazole and 2-ethyl-4,5-dimethyloxazole (3 equiv.), again the formation of mixtures of mono- and di-alkylation products **17a:17b** and **18a:18b** in 47:53 and 45:55 ratios was observed.

Scheme 5 Scope of the direct sp^3 functionalization of 2-methylimidazoles, 2-methyloxazoles or 2-alkylpyridines.^{13,14}

The reactivity of a few 2-alkylpyridine derivatives using K_2CO_3/DMA as reaction conditions was also studied (Scheme 6). A mixture of 1 equiv. of ethyl 2-bromomethylacrylate and 1.5 equiv. of 2-methylpyridine gave the products **19a** and **19b** in a 84:16 ratio. Under similar conditions, the coupling with 2,3-dimethylpyridine only gave **20a** in a very high yield. A high selectivity in favour of the formation on mono-coupling product **21a** was also observed with 2,4-dimethylpyridine.

Scheme 6 Scope of the direct sp^3 functionalization of 2-methylpyridines.^{13,14}

In summary, we have demonstrated that the sp^3 functionalisation of 2-alkyl substituents of azoles with a 2-bromomethylacrylate to form sp^3 - sp^3 carbon-carbon bonds proceeds using only K_2CO_3 as base without catalyst. The reaction selectively promotes the functionalization at C2-alkyl of thiazoles, oxazoles or imidazoles even in the presence of other alkyl substituents. These conditions offer routes for fast access to functionalised alkyl chains at C2 of these heteroarenes.
