Abstract

Different D-\(\pi\)-A push-pull molecules in which dipicolylamine (DPA) is used as the donor group, different diazines as the acceptor groups, and styryl as the \(\pi\)-conjugated spacer have been synthesized in a straightforward manner by aldol condensation of 4-(di-2-picolylamino)benzaldehyde and the appropriate methyldiazine. All of the compounds showed \(\pi\)-\(\pi^*\) transitions in the UV or visible region and the emission of yellow-green light upon irradiation. Significant red shifts were observed in the fluorescence emission maxima of these compounds on increasing the solvent polarity, a finding that suggests the formation of an intramolecular charge-separated emitting state that is also supported by semi-empirical
calculations. In some cases, protonation led to marked color changes, thus showing the ability
of these molecules to function as colorimetric pH sensors. The DPA and diazine units can act
as coordination sites for metal cations such as Zn$^{2+}$, Cd$^{2+}$ or Hg$^{2+}$, leading to a blue or red shift
in the fluorescence spectra due to the change in the intramolecular charge transfer properties.
This phenomenon could become a powerful tool for the creation of multiple emission colors
with a single molecule after suitable design.

**Keywords:** diazines; metal cations; fluorescence; intramolecular charge transfer; π-
conjugated systems

1. Introduction

During the past decade, donor-π-acceptor (D-π-A) push-pull systems that incorporate
diazine rings as electron-attracting units have been widely studied for their luminescence and
non-linear optical properties [1]. The fluorescence of these molecules relies heavily on the
nature of the donor and acceptor parts, and it can be easily modulated by several external
stimuli. For example, diazine derivatives have been developed as fluorescent sensors for
polarity [2], pH [2a,c,e,3], metal cations [4], proteins [5] and particular forms of DNA [6].
Most recently, 1,3-benzodiazine (quinazoline) units were used as electron-deficient segments
in D-π-A dyes that displayed solid-state white photoluminescence (PL) and
electroluminescence (EL) by doping a certain amount of acid into thin films, which has a
potential application in the fabrication of white organic light emitting diodes (OLEDs) [7].

In general, D-π-A push-pull systems are highly sensitive to metal coordination, which
can occur not only in the acceptor part of the molecule but also in the donor part [8]. Binding
in the A unit leads to a red shift in the emission spectra due to stronger stabilization of the
LUMO than the HOMO, which results in a lower HOMO-LUMO energy gap. In contrast,
interaction with the D unit results a blue shift of the fluorescence because the metal
coordination stabilizes the HOMO more strongly than the LUMO. Of particular interest are
molecules that possess metal-binding sites on both the electron-donor and -acceptor parts because such systems can show multiple fluorescence colors in response to several metal cation inputs [9]. In this context, Shiraishi et al. described a styrylquinoline dye with a dipicolylamine (DPA) moiety that showed multicolor fluorescence upon addition of different metal cations. For the first time, near white fluorescence was created by the addition of a mixture of Cd$^{2+}$ and Pb$^{2+}$ in an appropriate ratio [8a].

The diazine ring is an excellent candidate to be incorporated in such structures because of its high electron-withdrawing character and potential ligand properties. Thus, taking advantage of our experience in the synthesis of arylvinyl (styryl) diazines and benzodiazines [2a-b,e,6a,10], we report here the straightforward preparation of a series of D-π-A push-pull molecules in which DPA is used as a donor group and different diazine-based groups [pyridazine, pyrimidine, pyrazine, quinoxaline and di(pyridin-2-yl)pyrimidine] are used as acceptors. The DPA group is a strong electron donor that can act as a coordination site for metal cations and this unit has been widely used for the design of new fluorophores [8a,11]. On the other hand, we previously showed that 4-arylvinyl-2,6-di(pyridyn-2-yl)pyrimidines can coordinate various metal cations, such as Zn$^{2+}$, Sn$^{2+}$ and Ca$^{2+}$, to give a red-shifted emission [12].

The photophysical properties of the prepared compounds are also reported, including solvatochromism and the effect that treatment with acid and selected metal cations (Zn$^{2+}$, Cd$^{2+}$, Hg$^{2+}$) has on the luminescence properties.

2. Experimental

2.1. General.

4-(Di-2-picolylamino)benzaldehyde (I) [13] and 4-methyl-2,6-dipyridin-2-yl-pyrimidine [10e] were obtained as described previously. In air- and moisture-sensitive reactions, all glassware was flame-dried and cooled under nitrogen. NMR spectra were acquired at room
temperature on a Bruker AC-300 spectrometer. Chemical shifts are given in parts per million relative to TMS (\( ^1\text{H}, 0.0 \text{ ppm} \)) and CDCl\(_3\) (\( ^{13}\text{C}, 77.0 \text{ ppm} \)). Acidic impurities in CDCl\(_3\) were removed by treatment with anhydrous K\(_2\)CO\(_3\). High resolution mass analyses were performed at the “Centre Regional de Mesures Physiques de l’Ouest” (CRMPO, University of Rennes1) using a Bruker MicroTOF-Q II apparatus. UV/vis spectra were recorded on a Jasco V-530 spectrophotometer using standard 1 cm quartz UV cells. Fluorescence spectra were recorded on a Jasco FP-750 spectrofluorimeter. Compounds were excited at their absorption maxima (band of lowest energy) to record the emission spectra. The \( \Phi_F \) values were calculated using a well-known procedure with two different standards, quinine sulfate in 0.1 M H\(_2\)SO\(_4\) and 9,10-diphenylanthracene in cyclohexane [14]. Stokes shifts were calculated by considering the lowest energetic absorption band.

2.2. General Procedure for the synthesis of arylvinyldiazine (styryldiazines).

4-(Di-2-picolylamino)benzaldehyde (1) (110 mg, 0.36 mmol) and the appropriate methyldiazine derivative (0.72 mmol; 0.36 mmol for 4-methyl-2,6-dipyridin-2-yl-pyrimidine; 0.18 mmol for 4,6-dimethylpyrimidine) were dissolved in anhydrous THF (15 mL). K' BuO (1.44 mmol, 161 mg, 4 eq.) was slowly added at room temperature and the solution was heated under reflux for 15 h. The mixture was allowed to cool and water was added. THF was evaporated and the mixture was extracted with CH\(_2\)Cl\(_2\). The organic layer was dried over MgSO\(_4\) and the solvent was removed under vacuum. The crude product was purified by flash chromatography.

2.2.1. 4-[2-(4-Di-2-picolamino)phenyl]vinyl|pyrimidine 2a

The crude product was purified by flash chromatography (alumina, eluent: petroleum ether/ethyl acetate 1:1). Orange solid: 61% (82 mg). Mp: 144–145 °C. \( ^1\text{H} \) NMR (300 MHz, CDCl\(_3\)): \( \delta \) 4.87 (s, 4H), 6.73 (d, 2H, J = 8.7 Hz), 6.81 (d, 1H, J = 15.9 Hz), 7.20 (d, 1H, J = 2.1 Hz), 7.25–7.23 (m, 4H), 7.42 (d, 2H, J = 8.7 Hz), 7.67–7.61 (m, 2H), 7.76 (d, 1H, J = 15.9 Hz).
Hz), 8.63–8.56 (m, 3H), 9.07 (s, 1H). $^{13}$C NMR and JMOD (75 MHz, CDCl$_3$): $\delta$ 162.9 (C), 158.1 (C), 156.8 (CH), 149.81 (CH), 149.76 (CH), 149.4 (C), 137.5 (CH), 136.9 (CH), 129.4 (CH), 124.7 (C), 122.3 (CH), 121.2 (CH), 120.8 (CH), 118.0 (CH), 112.7 (CH), 57.2 (CH$_2$).

HRMS (ESI/ASAP): $m/z$ calculated for C$_{24}$H$_{22}$N$_5$ [M + H]$^+$ 380.1875, found 380.1882.

2.2.2. 4-[2-(4-Di-2-picolylaminophenyl)vinyl]-2,6-dipyridin-2-yl-pyrimidinene 2b

The crude product was purified by flash chromatography (alumina, eluent: ethyl acetate/isopropanol 9:1) followed by crystallization from CH$_2$Cl$_2$/n-heptane. Orange solid: 64% (123 mg). Mp: 84–86 °C. $^1$H NMR (300 MHz, CDCl$_3$): $\delta$ 4.90 (s, 4H), 6.75 (d, 2H, $J = 8.4$ Hz), 7.26–7.17 (m, 5H), 7.43 (t, 2H, $J = 6.0$ Hz), 7.51 (d, 2H, $J = 8.4$ Hz), 7.67 (t, 2H, $J = 7.5$ Hz), 7.97–7.88 (m, 3H), 8.44 (s, 1H), 8.64–8.62 (m, 2H), 8.77–8.67 (m, 3H), 8.90 (d, 1H, $J = 4.2$ Hz). $^{13}$C NMR and JMOD (75 MHz, CDCl$_3$): $\delta$ 165.6 (C), 163.4 (C), 163.0 (C), 158.2 (C), 155.6 (C), 154.5 (C), 150.0 (CH), 149.8 (CH), 149.4 (CH), 149.3 (C), 137.6 (CH), 137.0 (CH), 136.9 (CH), 136.8 (CH), 129.4 (CH), 125.2 (CH), 125.2 (C), 124.5 (CH), 123.9 (CH), 122.8 (CH), 122.2 (CH), 122.1 (CH), 120.8 (CH), 112.6 (CH), 112.2 (CH), 57.2 (CH$_2$). HRMS (ESI/ASAP): $m/z$ calculated for C$_{34}$H$_{28}$N$_7$ [M + H]$^+$ 534.2406, found 534.2413.

2.2.3. 2-[2-(4-Di-2-picolylaminophenyl)vinyl]pyrazine 2c

The crude product was purified by flash chromatography (alumina, eluent: petroleum ether/ethyl acetate 1:1). Yellow solid: 63% (85 mg). Mp: 150–151 °C. $^1$H NMR (300 MHz, CDCl$_3$): $\delta$ 4.87 (s, 4H), 6.72 (d, 2H, $J = 8.7$ Hz), 6.91 (d, 1H, $J = 15.9$ Hz), 7.24–7.17 (m, 4H), 7.42 (d, 2H, $J = 8.7$ Hz), 7.65–7.59 (m, 3H), 8.31 (d, 1H, $J = 2.4$ Hz), 8.46 (d, 1H, $J = 2.4$ Hz), 8.55 (s, 1H), 8.62–8.60 (m, 2H). $^{13}$C NMR and JMOD (75 MHz, CDCl$_3$): $\delta$ 158.3 (C), 149.8 (CH), 149.0 (C), 144.1 (CH), 143.4 (CH), 142.0 (C), 141.4 (CH), 136.9 (CH), 135.1 (CH), 128.8 (C), 125.3 (CH), 122.2 (CH), 120.8 (CH), 119.9 (CH), 112.7 (CH), 57.3 (CH$_2$). HRMS (ESI/ASAP): $m/z$ calculated for C$_{25}$H$_{22}$N$_5$ [M + H]$^+$ 380.1875, found 380.1880.
2.2.4. 2-[2-(4-Di-2-picolylaminophenyl)vinyl]quinoxaline 2d

The crude product was purified by flash chromatography (alumina, eluent: petroleum ether/ethyl acetate 1:1). Yellow solid: 84% (129 mg). Mp 112–113 °C. $^1$H NMR (300 MHz, CDCl$_3$): $\delta$ 4.88 (s, 4H), 6.75 (d, 2H, $J = 8.7$ Hz), 7.13 (d, 1H, $J = 15.9$ Hz), 7.21–7.18 (m, 2H), 7.27–7.24 (m, 2H), 7.48 (d, 2H, $J = 8.7$ Hz), 7.68–7.62 (m, 4H), 7.75 (d, 1H, $J = 15.9$ Hz), 8.03–7.99 (m, 2H), 8.62–8.60 (m, 2H), 8.97 (s, 1H). $^{13}$C NMR and JMOD (75 MHz, CDCl$_3$): $\delta$ 158.2 (C), 151.4 (C), 149.9 (CH), 149.2 (CH), 144.5 (CH), 142.6 (C), 141.2 (C), 136.9 (CH), 136.4 (CH), 130.1 (CH), 129.1 (CH), 128.9 (CH), 128.6 (CH), 125.3 (C), 122.2 (CH), 121.2 (CH), 120.8 (CH), 112.7 (CH), 57.2 (CH$_2$). HRMS (ESI/ASAP): $m/z$ calculated for C$_{28}$H$_{23}$N$_5$Na [M + Na]$^+$ 452.1851, found 452.1851.

2.2.5. 3-[2-(4-Di-2-picolylaminophenyl)vinyl]pyridazine 2e

The crude product was purified by flash chromatography (alumina, eluent: petroleum ether/ethyl acetate 1:1). Yellow solid: 64% (86 mg). Mp: 171–172 °C. $^1$H NMR (300 MHz, CDCl$_3$): $\delta$ 4.88 (s, 4H), 6.74 (d, 2H, $J = 8.7$ Hz), 7.13 (d, 1H, $J = 16.2$ Hz), 7.22–7.18 (m, 2H), 7.37 (dd, 1H, $J_1 = 4.8$ Hz, $J_2 = 8.7$ Hz), 7.44 (d, 2H, $J = 8.7$ Hz), 7.59–7.54 (m, 2H), 7.68–7.62 (m, 2H), 8.62–8.61 (m, 2H), 8.97 (dd, 1H, $J_1 = 1.5$ Hz, $J_2 = 4.8$ Hz). $^{13}$C NMR and JMOD (75 MHz, CDCl$_3$): $\delta$ 159.0 (C), 158.9 (C), 158.3 (C), 149.8 (CH), 148.5 (CH), 136.9 (CH), 135.0 (C), 128.9 (CH), 126.2 (CH), 125.2 (C), 123.4 (CH), 122.2 (CH), 121.0 (CH), 120.8 (CH), 112.7 (CH), 57.3 (CH$_2$). HRMS (ESI/ASAP): $m/z$ calculated for C$_{24}$H$_{22}$N$_5$ [M + H]$^+$ 380.1875, found 380.1879.

2.2.6. 4,6-Bis[2-(4-di-2-picolylaminophenyl)vinyl]pyrimidine 3

The crude product was purified by flash chromatography (alumina, eluent: petroleum ether/ethyl acetate 1:1). Orange solid: 52% (64 mg). Mp: 110–112 °C. $^1$H NMR (300 MHz, CDCl$_3$): $\delta$ 4.87 (s, 8H), 6.72 (d, 4H, $J = 8.7$ Hz), 6.80 (d, 2H, $J = 15.9$ Hz), 7.10 (s, 1H), 7.22–
7.18 (m, 8H), 7.42 (d, 4H, \( J = 8.7 \) Hz), 7.66–7.60 (m, 4H), 8.61–8.59 (m, 4H), 8.95 (s, 1H). \(^{13}\)C NMR and JMOD (75 MHz, CDCl\(_3\)): \( \delta \) 163.0 (C), 158.2 (C), 149.2 (C), 136.9 (CH), 136.6 (CH), 129.3 (CH), 125.0 (C), 122.2 (CH), 122.1 (CH), 121.7 (CH), 120.85 (CH), 120.77 (CH), 112.6 (CH), 57.2 (CH\(_2\)). HRMS (ESI/ASAP): \( m/z \) calculated for C\(_{44}\)H\(_{39}\)N\(_8\) [M + H]\(^+\) 679.3292, found 679.3284.

3. Results and Discussion

3.1. Preparation of Styryldiazine Derivatives.

Styryldiazine derivatives are generally obtained by aldol condensation of aldehydes with methyldiazenes in basic media [2,5,6a,10,15]. In this way, the target compounds 2a–e were prepared in moderate-to-good yield by this well-established protocol from 4-(di-2-picolylamino)benzaldehyde (1) and the corresponding methyldiazine in refluxing THF using potassium tert-butoxide as the base (Scheme 1). The 4,6-distyrylpyrimidine derivative 3 was also obtained in moderate yield starting from 4,6-dimethylpyrimidine.

The new compounds exhibited good solubility in a variety of solvents, especially in THF, acetonitrile and chlorinated solvents, which allowed unequivocal characterization by NMR spectroscopy. The \( ^3J(H,H) \) coupling constants of \( \sim 16.0 \) Hz for the vinylic protons in the \(^1\)H NMR spectra indicated the selective formation of trans-configured double bonds in all condensation reactions.

3.2. UV-vis and Fluorescence Spectroscopy.

The photophysical properties of compounds 2 and 3 were examined by UV-vis and fluorescence spectroscopy in acetonitrile at 25 °C and the results are summarized in Table 1. As one would expect, all of the absorption spectra showed a similar pattern with a \( \pi-\pi^* \) transition in the UV or visible region at \( \lambda_{\text{max}} = 364–410 \) nm accompanied by one or two extra bands at higher energy (Figure 1, see also Supporting Information). Typical emission maxima
were obtained in the green-yellow region on irradiating the solutions. Pyrazine derivative 2c exhibited the highest fluorescence quantum yield ($\Phi_F = 0.24$). In a similar way to other styryldiazine compounds [10d], quinoxaline derivative 2d showed a red-shifted absorption and emission band when compared to pyrimidine (2a), pyrazine (2c) and pyridazine (2e) derivatives. As far as pyrimidine derivatives are concerned, the introduction of pyridin-2-yl substituents at positions 2 and 4 of the pyrimidine ring in 2b led to bathochromic shifts in the absorption and emission spectra. Comparable red shifts were observed on going from 4-styrylpyrimidine 2a to 4,6-distyrylpyrimidine 3, as observed previously for related systems [2b].

$^a$ All spectra were recorded in acetonitrile solutions at room temperature at $c = 5.3–12.8 \times 10^{-6}$ M. $^b$ Fluorescence quantum yield ($\pm 10\%$) determined relative to quinine sulfate in 0.1 M H$_2$SO$_4$ ($\Phi_F = 0.54$) and 9,10-diphenylanthracene in cyclohexane ($\Phi_F = 0.90$) as standards.

It is worth noting that the fluorescence spectra showed significant solvatochromism (Table 2). An increase in the solvent polarity led to bathochromic shifts of the emission maxima, although the solvatochromic range was lower than for dimethylamino analogs [10d]. As an example, the spectra registered for compound 2b are shown in Figure 2, where the maximum emission wavelength at $\lambda_{\text{em}} = 473$ nm in the least polar solvent (cyclohexane) is
red-shifted by about 95 nm (Δν_{em} = 3536 cm⁻¹) in DMSO (λ_{em} = 568 nm). This finding supports a highly polarized excited singlet state generated by the intramolecular charge transfer from the donor dipicolylamino group to the acceptor diazine groups. The large Stokes shifts (Table 1) are also indicative of the high polarizability of these systems due to the presence of both donor and acceptor groups coupled by a π-conjugated spacer. Nevertheless, solvatochromism is almost negligible in the absorption spectra, suggesting the absence of a significant electronic interaction between groups in the ground state.

\(^a\) Dimroth–Reichardt polarity parameter,\(^b\) kcal·mol⁻¹. \(^b\) Δν_{em} = ν (cyclohexane) – ν (DMSO). \(^c\) Using the more energetic emission band in cyclohexane.

Acetonitrile solutions of compounds 2d and 3 underwent significant color changes upon addition of TFA (Figure 3). Initially DPA is the most basic moiety in both molecules, but the electron-donating character of the DPA styryl chain increases the basicity of the quinoxaline and pyrimidine heterocyclic rings and makes it difficult to envisage the structure of the protonated species. We previously observed this phenomenon in related diazines and demonstrated the potential of these compounds as colorimetric pH sensors [2a,2e,6a,10c–e].
On the other hand, the emission was totally quenched after treatment with acid, as is generally observed for amino electron donor substituted diazines [2a,10d].

(Figure 3.)

The emission properties of compounds 2a–d were also investigated in the presence of an excess of the metal cations Zn$^{2+}$, Cd$^{2+}$ and Hg$^{2+}$. The results are presented in Table 3. Different types of behavior were observed depending on the nature of the diazine ring. The addition of Zn$^{2+}$, Cd$^{2+}$ or Hg$^{2+}$ led to a red shift associated with significant quenching of the fluorescence intensity in the case of pyrimidine derivatives 2a–b, whereas a blue shift was observed for pyrazine and quinoxaline derivatives 2c and 2d. The emission spectra and fluorescence color changes observed for pyrazine derivative 2c are shown in Figures 4 and 5, respectively. It can be observed that only a moderate decrease in the fluorescence quantum yield was detected: $\Phi_F(2c) = 0.24$, $\Phi_F(2c + Zn^{2+}) = 0.04$ and $\Phi_F(2c + Cd^{2+}) = 0.12$.

The emission characteristics are due to the different intramolecular charge transfer (ICT) properties of these push-pull molecules in response to coordination of the respective metal cations. Both the diazine and DPA groups can act as the metal binding site. Initially, the blue shift in 2c–d indicates a decreased CT into the molecules due to coordination of the metal cation on the DPA electron-donating group. Analogously, the red shift in 2a–b could be explained by extra binding of the metal cation on the electron-attracting part of the pyrimidine, as reported for a related compound [8a]. Indeed, pyrimidine is a stronger base than pyrazine and quinoxaline. These results show that metal cations can be used as external stimuli for the modulation of emission colors in these systems. Nevertheless, further quantitative investigations are required to determine the optimum stoichiometry and coordination properties. This work is currently in progress in our laboratories.

3.3. Calculations.

The HOMO and LUMO levels, their differences as well as the ground state dipole moments of target compounds 2a-e and 3 were studied by semi-empirical calculations. Initial geometries were calculated by PM3 implemented in ArgusLab [17] and subsequently optimized by PM7 in MOPAC [18]. The calculated values are summarized in Table 4. Figure 6 shows the optimized geometries and the HOMO and LUMO localizations for each particular derivative [19].

Table 4. PM7 calculated parameters of molecules 2a-e and 3

| Compd | $E_{\text{HOMO}}$ [eV] | $E_{\text{LUMO}}$ [eV] | $\Delta E$ [eV] | $\mu$ [D] | $\lambda_{\text{abs}}$ [eV]

$^a$ Experimental longest-wavelength absorption maxima measured in acetonitrile (1240/$\lambda_{\text{abs}}$).

The calculated energies of the HOMO and LUMO range from -8.25 to -8.16 and -1.11 to -0.79 eV, respectively. Although these values are generally overestimated and should be treated with precaution, the calculated HOMO-LUMO gaps ($\Delta E$) for 2a-e correlates well with the position of the experimentally obtained longest-wavelength absorption maxima ($R^2 = 0.8$). Hence, the PM7 calculations are capable to describe the trends within this series of molecules.
Although the changes in $\Delta E$ are relatively small, some structure-property relationships can be elucidated. When going from 2a to 2b, the gap has decreased by 0.09 eV as a result of attaching two pyridine-2-yl rings to the pyrimidine acceptor. The replacement by a pyrazine ring (2a to 2c) lowered the gap negligibly by 0.05 eV. However, its further extension by a fused benzene ring as in 2d resulted in the lowest gap of 7.09 eV. Pyridazin-3-yl acceptor in 2e delivered very similar HOMO-LUMO gap ($\Delta E = 7.25$ eV) as pyrimidin-4-yl (2a; $\Delta E = 7.27$ eV) and pyrazine-3-yl (2c; $\Delta E = 7.22$ eV).

>Figure 6.<

The HOMO and LUMO visualizations shown in Figure 6 clearly show charge separation and thus further confirms ICT character of molecules 2a-e and 3. As expected, the HOMO is predominantly localized on the amino donor and the adjacent $\pi$-system, whereas the LUMO is spread over the diazine acceptors.

**4. Conclusions**

A series of push-pull dipicolylamine styryldiazine derivatives has been efficiently synthesized by aldol condensation between 4-(di-2-picolylamino)benzaldehyde and the appropriate methylidiazine. The new compounds were fully characterized. All of the molecules presented absorption wavelengths in the UV or visible region and emit light with significant Stokes shifts. The presence of both a donor and an acceptor group coupled by a $\pi$-conjugated spacer enables intramolecular charge transfer processes that lead to highly polarized singlet excited states. This situation is reflected by large red shifts in the fluorescence emission maxima upon increasing the solvent polarity and supported by semi-empirical calculations. As in other related diazines, 2d and 3 undergo significant color change upon addition of acid and this property highlights their potential as colorimetric pH sensors. Moreover, the addition of
different metal cations resulted in blue or red shifts in the fluorescence spectra and this effect may become a powerful tool for the development of multicolor emitters.
