Abstract

In this paper, color-tunable Gd₂O₂CN₂:Tb³⁺,Eu³⁺ phosphors were obtained by co-doping Eu³⁺ and Tb³⁺ ions into Gd₂O₂CN₂ host and singly varying the Eu³⁺ doping concentration. The characteristics of the crystal structure, photoluminescence lifetime and photoluminescence of Tb³⁺,Eu³⁺ single-doped and Tb³⁺ and Eu³⁺ co-doped Gd₂O₂CN₂, were carefully investigated by XRD, FTIR, PL decay curves and photoluminescence (PL). The results indicated that Tb³⁺ single-doped Gd₂O₂CN₂ phosphor show a green emission, and by increasing Eu³⁺ content, Gd₂O₂CN₂:Tb³⁺, Eu³⁺ phosphors emit green to orange and then to red light under the excitation of 379nm.

Keywords: Photoluminescence; Gd₂O₂CN₂:Tb³⁺, Eu³⁺; color-tunable phosphors

1. Introduction

During the past few years, rare earth oxycyanamide compounds as host materials have received much attention due to their outstanding luminescence properties when doped with rare-earth ions[1-3]. The structures of RE₂O₂CN₂ and RE₂O₂S are closely related [4] and previous work has

shown that the luminescence properties of $\text{RE}_2\text{O}_2\text{S}:\text{Eu}^{3+}$ (RE=Gd and Y) and $\text{RE}_2\text{O}_2\text{CN}_2:\text{Eu}^{3+}$ (RE=Gd and Y) are quite similar [5, 6]. Therefore, such oxycyanamide compounds are considered to be efficient host candidates for rare-earth activators ions such as Eu^{3+} and Tb^{3+} for instance. Eu^{3+} is considered as an important activator ion with red emission corresponding to the transition of $^5\text{D}_0-^7\text{F}_j$ ($J=1-6$) [7]. The emission of Tb^{3+} is due to the transition between the emitting states of $^5\text{D}_j$ and the excited states of $^7\text{F}_j$, and the main intense green emission is attributed to the transition of $^5\text{D}_4-^7\text{F}_5$ which is located at ca. 543nm[8].

In the previous study, we have reported the strong red emission of Eu^{3+} doped $\text{Gd}_2\text{O}_2\text{CN}_2$ phosphors [9]. In this work, we report a new color tunable phosphor $\text{Gd}_2\text{O}_2\text{CN}_2:\text{Tb}^{3+}, \text{Eu}^{3+}$. A series of $\text{Tb}^{3+}, \text{Eu}^{3+}$ singly-doped and $\text{Tb}^{3+}-\text{Eu}^{3+}$ co-doped phosphors were successfully prepared by classical solid state reaction at low firing temperature (750 °C). The emitting color of $\text{Gd}_2\text{O}_2\text{CN}_2:\text{Tb}^{3+}, \text{Eu}^{3+}$ phosphors can be tuned from green to orange and then to red by singly varying the doping concentration of Eu^{3+} . The mechanism of energy transfer between Tb^{3+} and Eu^{3+} was investigated, and the results show that $\text{Eu}^{3+}/\text{Tb}^{3+}$ co-doped $\text{Gd}_2\text{O}_2\text{CN}_2$ phosphors could serve as potential phosphors for NUV LEDs.

2. Experimental

Powder samples with the general formula $\text{Gd}_{2-x}\text{Tb}_x\text{O}_2\text{CN}_2$ [$x=0.03(\text{T-1}), 0.05(\text{T-2}), 0.07(\text{T-3}), 0.12(\text{T-4}), 0.15(\text{T-5})$ and $0.20(\text{T-6})$], $\text{Gd}_{1.90}\text{Eu}_{0.1}\text{O}_2\text{CN}_2$ (GOCN-4) and $\text{Gd}_{1.85-y}\text{Tb}_{0.15}\text{Eu}_y\text{O}_2\text{CN}_2$ [$y=0.02(\text{ET-1}), 0.04(\text{ET-2}), 0.06(\text{ET-3}), 0.08(\text{ET-4}), 0.10(\text{ET-5}), 0.15(\text{ET-6})$] were prepared by solid state reaction. High purity GdF_3 (99.99%), Eu_2O_3 (99.99%), Tb_4O_7 (99.99%), Li_2CO_3 (99.99%), and active carbon (CARBIO 12 SA—ref: C1220 G 90) as the raw materials were thoroughly mixed and fired at 600 °C for 9 h, then 750 °C for 12 h under NH_3 atmosphere. The

detailed synthesis routes can be found in literature [9].

Powder X-ray diffraction (XRD) data were recorded using a Bruker AXS D8 Advance diffractometer (Voltage 50 kV, current 40 mA, Cu-K α). Photoluminescence (PL) and photoluminescence excitation (PLE) spectra were measured by a Fluorolog-3-P UV-vis-NIR fluorescence spectrophotometer (Jobin Yvon, longjumeau, France) with a 450 W Xenon lamp as the excitation source. The decay curves of Tb³⁺ emission was performed by FLSP920 (Edinburgh Instruments). The FTIR spectrum was measured in transmission mode using a KBr standard (Bruker, Model vector 22). The color chromaticity coordinates were obtained according to Commission Internationale de l'Eclairage (CIE) using Radiant Imaging color calculator software.

3. Results and discussion

As shown in Figure 1, the XRD patterns of the Tb³⁺ and/or Eu³⁺ activated Gd₂O₂CN₂ samples can be readily indexed as a trigonal phase and identified as Gd₂O₂CN₂ with the space group P-3m1 according to the JCPDS database (PDF#49-1169). Considering the similar coordinated environment, electronegativity and ionic radii of Gd³⁺ (r=0.100nm, CN=7), Tb³⁺ (r=0.098nm, CN=7) and Eu³⁺ (r=0.101nm, CN=7) ions, doping Tb³⁺ and Eu³⁺ does not result in any phase transformation and only has minor influence to the crystal structure.

Figure 2 shows the IR spectra of GOCN-4, ET-5 and T-5. IR spectra for ET-5 and T-5 both have the intense peaks at 2080 and 652 cm⁻¹. In our previous study we reported that the typical absorption peaks in the vicinity of 2010 and 652 cm⁻¹ in the GOCN-4 were respectively assigned to the ν_2 (bending vibration) and ν_3 (asymmetric stretching vibration) modes of the CN₂²⁻ ion [9]. Hence, the IR spectra also indicate that CN₂²⁻ ions contained in Eu³⁺, Tb³⁺ single-doped and Eu³⁺-Tb³⁺ co-doped Gd₂O₂CN₂ samples.

Figure 3 illustrates the excitation (monitored at 543 nm) and emission (excited by 280, 313 and 365 nm) spectra of the T-5 sample (7.5 at. % Tb^{3+}). The excitation spectrum (Fig. 3a) exhibits a broad and intense band in the range from 250 to 300 nm with a peak at around 280 nm. This broad band is attributed to $4f^8-4f^75d^1$ transitions of Tb^{3+} ions. The other excitation bands at longer wavelengths, are located at 307 nm ($^5H_5 \rightarrow ^7F_6$), 313 nm ($^5H_5 \rightarrow ^7F_5$) and 350-380nm (transitions from 7F_4 , 7F_3 to 5H_7 , 5D_0 , 5D_1). The emission spectra of T-5 (Fig. 3b) at different excitation wavelengths are very similar both in shape and relative intensities. The strongest peak split into two at 543 and 550 nm corresponds to the $^5D_4 \rightarrow ^7F_5$ transition, while the peaks at 487 and 495nm, 587nm, and 622nm respectively originate from the $^5D_4 \rightarrow ^7F_6$, $^5D_4 \rightarrow ^7F_4$ and $^5D_4 \rightarrow ^7F_3$ transitions of Tb^{3+} ions.

The excitation (monitored at 543nm) and emission (monitored at 280nm) spectra of $Gd_{2-x}Tb_xO_2CN_2$ with varying Tb^{3+} concentrations ($x=0.03, 0.05, 0.07, 0.12, 0.15$ and 0.20) are shown in Fig. 4. With the increase of doped Tb^{3+} ions concentration, the excitation and the emission intensity increases gradually ranging from 1.5 to 7.5 at. % and decreases from 7.5 to 10 at. %, which is in accordance with Eu^{3+} doped $Gd_2O_2CN_2$ in previous work [9]. Considering the mechanism of energy transfer in phosphors, the concentration quenching can be explained in more details by the critical distance (R_c) between Tb^{3+} ions which can be calculated by Eq. (1) [10]:

$$R_c = 2 \times (3V / 4\pi X_c N)^{1/3} \quad (1)$$

Where V (101.9 \AA^3) is the volume of the unit cell, X_c (0.075) is the critical concentration of Tb^{3+} ions and N (2) is the number of lattice sites in the unit cells that can be occupied by Tb^{3+} ions. Therefore, R_c between Tb^{3+} ions is calculated to be 10.907 \AA .

PL and PLE spectra of singly-doped Eu^{3+} (GOCN-4, 5 at. %) or Tb^{3+} (T-5, 7.5 at. %) and

Eu³⁺/Tb³⁺ (ET-1, 1at. %/ 7.5 at. %) co-doped Gd₂O₂CN₂ phosphors are presented in Fig. 5. The excitation spectrum of GOCN-4 exhibits a broad and intense band in the range from 250 to 350 nm with a peak at around 300 nm, which is attributed to the ligand-to-metal charge transfer between O²⁻ and Eu³⁺. The weak excitation bands at longer wavelength corresponding to the 4f-4f transitions of Eu³⁺ are located at 379nm (⁷F₀→⁵G₂), 395nm (⁷F₀→⁵L₆), 467nm (⁷F₀→⁵D₂). Upon excitation at 300nm, the emission spectrum shows two strong peaks at 614 and 626 nm which originate from the ⁵D₀→⁷F₂ transition of Eu³⁺. Fig. 5 (b) shows the excitation and emission spectra of T-5, an intensive broad excitation band with the maximum at 280nm and other peaks at 313 and 379nm are observed. Upon the excitation at 280nm, the emission spectrum shows a strong peak at 543nm which is attributed to the transition ⁵D₄-⁷F₅ of Tb³⁺. Fig. 5 (c) shows the excitation spectra of ET-1 monitored at 626 and 543nm, the excitation band at around 379nm can be observed in both excitation spectra. The emission spectrum of ET-1 shows typical peaks at 543nm that originated from transition ⁵D₄-⁷F₅ of Tb³⁺ and at 614 and 626nm from transition ⁵D₀→⁷F₂ of Eu³⁺.

The emission spectra of Gd_{1.85-y}Tb_{0.15}Eu_yO₂CN₂ (0 ≤ y ≤ 0.15) are illustrated in Fig. 6. All samples exhibit two prominent peaks peaking at 543 and 626nm under 379nm excitation. By increasing the concentration of Eu³⁺, the emission intensities of Tb³⁺ at 543nm decrease remarkably while the emission intensity of Eu³⁺ at 626nm initially increases and then reaches a maximum at y=0.10, then decreases due to the concentration quenching. Therefore, we can speculate about the existence of energy transfer from Tb³⁺ to Eu³⁺ cations, such an energy transfer has also been observed in Y₂O₃[11], Ca₈MgLu(PO₄)₇ [12]and SrMg₂La₂W₂O₁₂ host materials[13].

To further certify the energy transfer from Tb³⁺ to Eu³⁺ ions in Gd₂O₂CN₂ host matrix, the PL decay curves were measured (excited at 379nm and monitored at 543nm) and the lifetimes of

different samples were calculated. Fig. 7 shows the decay curves of Tb^{3+} ions which can be well fitted to a double-exponential function as the following equation [14]:

$$I = I_0 + A_1 \exp(-t / \tau_1) + A_2 \exp(-t / \tau_2) \quad (1)$$

Where I is the luminescent intensity at the time of t and I_0 is the luminescent intensity at the time of 0; A_1 and A_2 are fitting parameters; τ_1 and τ_2 are rapid and slow lifetimes for exponential components, respectively. Based on these parameters, the average lifetime of Tb^{3+} ions with different Eu^{3+} concentration can be calculated by the following equation:

$$\tau = (A_1 \tau_1^2 + A_2 \tau_2^2) / (A_1 \tau_1 + A_2 \tau_2) \quad (2)$$

The effect of Eu^{3+} content on the calculated Tb^{3+} ions lifetimes was shown in the Fig. 7 inset, the decay lifetime of Tb^{3+} ions decrease with increasing Eu^{3+} concentration, which strongly supported the energy transfer from Tb^{3+} ions to Eu^{3+} ions.

Table 1 summarizes the CIE chromaticity coordinates of $\text{Gd}_{1.85-y}\text{Tb}_{0.15}\text{Eu}_y\text{O}_2\text{CN}_2$ ($0 \leq y \leq 0.20$) phosphors under the excitation at 379nm, Figure 8 also gives the CIE chromaticity coordinates, and it is interesting to notice that with the increasing of Eu^{3+} ions concentration, the CIE chromaticity coordinates shift from (0.3134, 0.5454) to (0.5682, 0.3322), the emitting color turned from green to red accordingly. The inset of Fig. 8 also shows the digital photos of $\text{Gd}_{1.85}\text{Tb}_{0.15}\text{O}_2\text{CN}_2$ (a), $\text{Gd}_{1.83}\text{Tb}_{0.15}\text{Eu}_{0.02}\text{O}_2\text{CN}_2$ (b) and $\text{Gd}_{1.70}\text{Tb}_{0.15}\text{Eu}_{0.15}\text{O}_2\text{CN}_2$ (g) phosphors under excitation at 379nm light. With the development of chip technology, high-performance InGaN-based 380 nm UV LEDs are fabricated [15] and commercially available NUV InGdN LED chip from 375 to 380nm is more and more common. Therefore, Eu^{3+} , Tb^{3+} co-doped $\text{Gd}_2\text{O}_2\text{CN}_2$ phosphors may have potential applications for NUV LEDs.

4. Conclusion

In this paper, Eu^{3+} , Tb^{3+} singly doped and Eu^{3+} - Tb^{3+} co-doped $\text{Gd}_2\text{O}_2\text{CN}_2$ phosphors were successfully prepared by classical solid-state reaction. The Tb^{3+} doped $\text{Gd}_2\text{O}_2\text{CN}_2$ phosphors exhibit a characteristic green emission with the strong peak at 543nm. The optimized Tb^{3+} concentration of $\text{Gd}_2\text{O}_2\text{CN}_2:\text{Tb}^{3+}$ is 7.5 at. %. When Eu^{3+} and Tb^{3+} were co-doped into $\text{Gd}_2\text{O}_2\text{CN}_2$, an efficient energy transfer from Tb^{3+} to Eu^{3+} occurred and thus by only increasing the doping concentration of Eu^{3+} , it becomes possible to tune the emission color from green to orange and then to red under the excitation at 379nm.
