## ABSTRACT

Reactions between $\left[\mathrm{Ru}(\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{CH})(\mathrm{dppe}) \mathrm{Cp}^{*}\right]$ and $\left[\mathrm{M}_{2}(\mathrm{NCMe})_{\mathrm{x}}(\mathrm{dppm})_{2}\right]^{2+}(\mathrm{M}=\mathrm{Cu}, \mathrm{x}=4$;
$\mathrm{Ag}, \mathrm{x}=2)$ have given complexes containing $\mathrm{M}_{3}(\mu \text {-dppm })_{3}$ clusters attached to one or two $-C \equiv C C \equiv C\left[R u(d p p e) C p^{*}\right]$ groups. Single crystal X-ray studies are recorded for $\left[\left\{M_{3}(\mu-\right.\right.$ dppm $\left.)_{3}\right\}\left\{\mu_{3}-\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}\left[\mathrm{Ru}(\right.\right.$ dppe $\left.\left.\left.) \mathrm{Cp}^{*}\right]\right\}\right]\left(\mathrm{BF}_{4}\right)_{2} \cdot \mathrm{nS}(\mathrm{M}=\mathrm{Cu}, \mathrm{Ag})$ [isomorphous (orthorhombic) for $\mathrm{S}=$ (ill-defined) acetone]. A different (triclinic) polymorph has also been defined for $\mathrm{M}=\mathrm{Ag}, \mathrm{nS}=5 \mathrm{THF}$. Together with $\left[\left\{\mathrm{Cu}_{3}(\mu \text {-dppm })_{3}\right\}\left\{\mu_{3}-\right.\right.$ $\left.\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}[\mathrm{Ru}(\mathrm{dppe}) \mathrm{Cp} *]_{2}\right] \mathrm{PF}_{6} \cdot 4 \mathrm{Me}_{2} \mathrm{CO}$, the structures definitively confirm the complexes as clear examples of mono- or bis-diyndiyl- $\mathrm{M}_{3}$ systems, devoid of close approaches to the vacant $\mathrm{M}_{3}$ faces of the former by counterions in the case of their acetone solvates, except in the case of the $\mathrm{BF}_{4}$ counterion in the $\mathrm{AgBF}_{4}$ / thf solvate. Cyclic voltammetric studies suggest that there are only weak electronic interactions between the ruthenium centres in the bis(diynyl) complexes, consequent upon weak overlaps between the carbon chain and the $\mathrm{M}_{3}(\mu \text {-dppm })_{3}$ clusters, as confirmed by DFT calculations on model complexes [ $\left\{\mathrm{M}_{3}(\mu\right.$ $\left.\left.\mathrm{dHpm})_{3}\right\}\{\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}[\mathrm{Ru}(\mathrm{dHpe}) \mathrm{Cp}]\}_{\mathrm{n}}\right]^{3-\mathrm{n}}\left[\mathrm{n}=1,2 ; \mathrm{dHpm}=\mathrm{CH}_{2}\left(\mathrm{PH}_{2}\right)_{2}, \mathrm{dHpe}=\right.$ $\left.\mathrm{H}_{2} \mathrm{P}\left(\mathrm{CH}_{2}\right)_{2} \mathrm{PH}_{2}\right]$. The complexes $\left[\mathrm{Ag}_{3} \mathrm{Cl}_{2}(\mathrm{dppm})_{3}\right] \mathrm{PF}_{6},\left[\mathrm{M}_{3}(\mu-\mathrm{dppm})_{3}(\mathrm{X})\left\{\mu_{3^{-}}\right.\right.$
$\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}\left[\operatorname{Re}(\mathrm{CO})_{3}\left(\mathrm{Bu}_{2}^{\mathrm{t}}\right.\right.$-bpy $\left.\left.\left.)\right]\right\}\right] \mathrm{PF}_{6}\left(\mathrm{M}=\mathrm{Cu}, \mathrm{X}=\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}\left[\operatorname{Re}(\mathrm{CO})_{3}\left(\mathrm{Bu}_{2}{ }_{2}-\mathrm{bpy}\right)\right] ; \mathrm{M}=\mathrm{Ag}\right.$; $\mathrm{X}=\mathrm{Cl}),\left[\mathrm{Ag}_{6}(\mu \text {-dppm })_{4}\left\{\mathrm{C} \equiv \mathrm{CC}=\mathrm{C}\left[\operatorname{Re}(\mathrm{CO})_{3}\left(\mathrm{Bu}^{\mathrm{t}}{ }_{2}-\mathrm{bpy}\right)\right]\right\}_{4}\right]\left(\mathrm{PF}_{6}\right)_{2}$ have also been prepared and structurally characterised. In the $\mathrm{M}_{3}$ clusters, some asymmetry in the attachment of at least one of the $\mu_{3}$ ligands is apparent, which results from interactions with solvate molecules.

## 1. Introduction

Complexes containing metal centres linked by a conjugated carbon bridge have attracted great attention because of their potential applications in molecular electronics [1-6]. Among these complexes, many diyndiyl compounds $\left[\left\{\mathrm{L}_{n} \mathrm{M}\right\} \mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}\left\{\mathrm{ML}_{n}\right\}\right]$ (where $\mathrm{ML}_{n}$ is a redox-active metal-ligand fragment) have been prepared with Mo [7], W [8], Mn [9], Re [10,11], Fe [12], $\mathrm{Ru}[13,14], \mathrm{Ru}_{2}$ [15,16], Os [17] or Pt [18,19]. These complexes show medium to strong electronic interactions between the two redox-active metal termini through the conjugated $\mathrm{C}_{4}$ chain, detailed calculations using density functional theoretical (DFT) methods having afforded some insight into the mechanism of electron transfer. Some recent reviews are available,[20,21] while an extensive consideration of the application of quantum chemical methods to the descriptions of a variety of mixed-valence systems is also available.[22]

An exciting development in this chemistry has been the synthesis of bis(diyndiyl) complexes of the general formula $\left[\left\{L_{n} M\right\} C \equiv C C \equiv C\left\{M^{\prime \prime} L_{p}\right\} C \equiv C C \equiv C\left\{M^{\prime} L_{m}{ }_{m}\right\}\right]$, in which a central metal-ligand fragment provides a link between two metalla-diyndiyl groups which may be the same or different. The evaluation of any electronic communication through the central organometallic moiety is of particular interest here because of the possibility of the central fragment acting as an insulator, a conductor, or an amplifier. [23-27] However, there has been no systematic study of the electronic properties of this type of compound, as relatively few examples are known.

Oxidation of trans- $\left[\operatorname{Pd}\left\{\mathrm{C}=\mathrm{CC} \equiv \mathrm{C}\left[\operatorname{Re}(\mathrm{NO})\left(\mathrm{PPh}_{3}\right) \mathrm{Cp} *\right]_{2}\left(\mathrm{PEt}_{3}\right)_{2}\right] 1\right.$ gives a monocation, for which EPR studies showed that the unpaired electron is localised on one rhenium atom [28]. Electronic interaction between the two terminal ferrocenyl moieties has been found in cis- $\mathrm{Ru}(\mathrm{C} \equiv \mathrm{CFc})_{2}(\mathrm{dppm})_{2}$ and trans, trans, trans $-\mathrm{Ru}(\mathrm{C} \equiv \mathrm{CFc})_{2}(\mathrm{CO})(\mathrm{L})\left(\mathrm{PBu}_{3}\right)_{2}[\mathrm{~L}=$

## ACCEPTED MANUSCRIPT

CO , py, $\left.\mathrm{P}(\mathrm{OMe})_{3}\right],[29]$ and in trans $-\mathrm{Ru}(\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{CFc})_{2}(\mathrm{dppe})_{2} 2$, obtained from $\mathrm{RuCl}_{2}(\mathrm{dppe})_{2}$ and $\mathrm{FcC} \equiv \mathrm{CC} \equiv \mathrm{CH}$ in the presence of $\mathrm{NaPF}_{6}$ and $\mathrm{NEt}_{3}[30]$. The cyclic voltammogram (CV) of 2 contains three reversible oxidation waves, two at -0.12 V and +0.01 V (assigned to the Fc groups) and one at +0.40 V (for the $\mathrm{Ru}^{\mathrm{II}} / \mathrm{Ru}^{\mathrm{III}}$ system) (all redox potentials herein are referenced to the SCE ). The presence of the two Fc -centred processes is consistent with there being an interaction between them through the $-\mathrm{C}_{4}-\mathrm{Ru}-\mathrm{C}_{4}-$ chain. In this complex, the $\mathrm{Ru}(\text { dppe })_{2}$ moiety (a strong electron-donating group) acts as a conductor (even possibly an amplifier), as a result of the excellent overlap which occurs between the central Ru d orbitals and the $\pi$ orbitals of the $\mathrm{C}_{4}$ fragments.

1

We have described the complex $\left[\operatorname{Hg}\left\{\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}[\mathrm{Ru}(\mathrm{dppe}) \mathrm{Cp} *]_{2}\right]\right.$ 3, obtained from $\left[\mathrm{Ru}(\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{CH})(\mathrm{dppe}) \mathrm{Cp}^{*}\right]$ and $\mathrm{Hg}(\mathrm{OAc})_{2}$ [31]. This was found to have an unusually bent $\mathrm{Ru}-\mathrm{C}_{4}-\mathrm{Hg}-\mathrm{C}_{4}-\mathrm{Ru}$ sequence $\left[\mathrm{Hg}-\mathrm{C}-\mathrm{C} 166.5(2)^{\circ}\right.$ ], although DFT analysis of its electronic structure suggested that the bending was due to 'crystal packing forces'. Of more interest was

## ACCEPTED MANUSCRIPT

the finding that there is no Hg contribution to the HOMO of the model complex $\left[\operatorname{Hg}\left\{\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}\left[\mathrm{Ru}(\mathrm{dHpe}) \mathrm{Cp}^{*}\right]\right\}_{2}\right] \quad\left[\mathbf{3 - H} ; \mathrm{dHpe}=\mathrm{H}_{2} \mathrm{P}\left(\mathrm{CH}_{2}\right)_{2} \mathrm{PH}_{2}\right]$, thus precluding any electronic communication between the ruthenium termini, i.e., the Hg atom acts as an insulator. This was supported by cyclic voltammetry which showed only one 2-eoxidation process.

We have also reported that enhanced interaction occurs in the trimetallic complex trans- $\left\{\mathrm{Cp}^{*}(\mathrm{dppe}) \mathrm{Ru}\right\} \mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}\left\{\mathrm{Ru}(\mathrm{dppe})_{2}\right\} \mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}\left\{\mathrm{Ru}(\mathrm{dppe}) \mathrm{Cp}^{*}\right\}$ 4, as shown by DFT calculations to be the result of efficient overlap of the $\mathrm{C}_{4}$ orbitals with all metal fragments, the HOMO and HOMO-1 spanning all eleven atoms of the $\mathrm{Ru}-\mathrm{C}_{4}-\mathrm{Ru}-\mathrm{C}_{4}-\mathrm{Ru}$ chain [32].

4

More recently, the Berke group has described the complexes $\left\{\mathrm{X}(\text { depe })_{2} \mathrm{Fe}\right\}(\mathrm{C} \equiv \mathrm{C})_{2}\left\{\mathrm{Fe}(\text { depe })_{2} \mathrm{X}\right\} \quad\left[\mathrm{X}=(\mathrm{C} \equiv \mathrm{C})_{\mathrm{n}} \mathrm{SnMe}_{3}, \quad \mathrm{n}=1, \quad 2 ; \quad\right.$ depe $=$ bis(diethylphosphino)ethane], which was used to make highly conductive molecular wires. Cleavage of the $\mathrm{SnMe}_{3}$ groups occurred on interaction with gold electrodes to give $\mathrm{Au} .$.

$(\mathrm{C} \equiv \mathrm{C})_{\mathrm{n}}\left\{\mathrm{Fe}(\text { depe })_{2}\right\}(\mathrm{C} \equiv \mathrm{C})_{2}\left\{\mathrm{Fe}(\text { depe })_{2}\right\}(\mathrm{C} \equiv \mathrm{C})_{\mathrm{n}} .$. Au systems. In these, a strongly hybridised electronic system extends over the molecule-metal interfaces.[33]

There is a limited amount of information about complexes in which a polynuclear group links two diyndiyl-metal fragments. Ren's group has described complexes such as $\mathrm{Fc}(\mathrm{C} \equiv \mathrm{C})_{\mathrm{n}}\left\{\mathrm{Ru}_{2}(\mathrm{dmba})_{4}\right\}(\mathrm{C} \equiv \mathrm{C})_{\mathrm{n}} \mathrm{Fc}\left(\mathrm{Fc}=\right.$ ferrocenyl, $\mathrm{dmba}=N, N^{\prime}$-dimethylbenzamidinate, $\mathrm{n}=$ 1-4) in which strong electronic coupling between the Fc termini exists over a distance of up to $27 \AA .[34]$ Related studies involved $\left\{(\mathrm{Xap})_{4} \mathrm{Ru}_{2}\right\}(\mathrm{C} \equiv \mathrm{C})_{\mathrm{n}}\left\{\mathrm{Ru}_{2}(\mathrm{dmba})_{4}\right\}(\mathrm{C} \equiv \mathrm{C})_{\mathrm{n}}\left\{\mathrm{Ru}_{2}(\mathrm{Xap})_{4}\right\}$ [Xap $=2$-(3-methoxy- or 3,5-dimethoxy-anilino)pyridinate, $\mathrm{n}=2$ ], where voltammetric, spectroscopic and DFT methods demonstrated extensive delocalisation over 20 Å.[35] Further examples of $\operatorname{Fc}(\mathrm{C} \equiv \mathrm{C})_{\mathrm{n}} \quad(\mathrm{n}=1,2)$ linked by $\mathrm{Ru}_{3}(\mathrm{NNN})_{3} \quad\left(\mathrm{NNN}=2,2^{\prime}-\right.$ dipyridylamido), [36] $\mathrm{Pt}_{2}(\mathrm{dppm})_{2}$, [37] $\mathrm{Pt}_{6}\left(\mathrm{PBu}_{2}\right)_{4}(\mathrm{CO})_{4},[38] \mathrm{Cu}_{3}(\mathrm{dppm})_{3}$, [39] or $\mathrm{M}_{6}(\mathrm{dppm})_{2}$ clusters [40] are known, while a few complexes contain poly-yndiyl-metal fragments to which are bridged by $\mathrm{M}_{6}(\mathrm{dppm})_{2}$ clusters [41] or complexed to $\mathrm{Co}_{2}(\mathrm{CO})_{4}(\mathrm{~L})_{2}\left[\mathrm{~L}_{2}=(\mathrm{CO})_{2}\right.$, dppm] [42] or $\mathrm{Os}_{3}(\mathrm{CO})_{\mathrm{n}}(\mathrm{n}=10,11)[43,44]$ groups. Reactions of $\left\{\mathrm{Cp}\left(\mathrm{Ph}_{3} \mathrm{P}\right)_{2} \mathrm{Ru}\right\}_{2}\{\mu$ $\left.(\mathrm{C} \equiv \mathrm{C})_{\mathrm{n}}\right\} \quad(\mathrm{n}=1,2)$ with $\mathrm{Fe}_{2}(\mathrm{CO})_{9}$ afford $\left\{\mathrm{Cp}\left(\mathrm{Ph}_{3} \mathrm{P}\right)_{2} \mathrm{Ru}\right\} \mathrm{C}_{\mathrm{m}}\left\{\mathrm{Fe}_{3}(\mathrm{CO})_{9}\right\} \mathrm{C}_{\mathrm{m}}\left\{\mathrm{Ru}\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{Cp}\right\}(\mathrm{m}$ $=3,5$, resp.).[42]

In 1993, Gimeno and co-workers reported the syntheses and crystal structures of various trinuclear alkynyl- $\mathrm{Cu}(\mathrm{I})$ complexes such as $\left[\mathrm{Cu}_{3}(\mu-\mathrm{dppm})_{3}\left(\mu_{3}-\eta^{1}-\mathrm{C} \equiv \mathrm{CR}\right)_{2}\right] \mathrm{BF}_{4}$ (where $\mathrm{R}=\mathrm{Ph},{ }^{\mathrm{t}} \mathrm{Bu}, \mathrm{CH}_{2} \mathrm{OMe}$ ) [45]. Since then, a number of polynuclear $\mathrm{Cu}(\mathrm{I})$ and $\mathrm{Ag}(\mathrm{I})$ alkynyl complexes have been reported by Yam's group [46-48] and by others [49]. These are promising building blocks for the construction of rigid-rod oligomeric and polymeric materials and exhibit interesting properties such as luminescence and an ability to mediate electron delocalisation. They are generally obtained from the reactions of $\left[\mathrm{M}_{2}(\mu\right.$ dppm $\left.)_{2}(\mathrm{NCMe})_{\mathrm{n}}\right] \mathrm{X}_{2}\left([\mathbf{5 - M}] \mathrm{X}_{2}, \mathrm{M}=\mathrm{Cu}, \mathrm{n}=4 ; \mathrm{Ag}, \mathrm{n}=2 ; \mathrm{X}=\mathrm{BF}_{4}, \mathrm{PF}_{6}\right)$ with a terminal alkyne in the presence of an excess of KOH or dbu in refluxing $\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{MeOH}$ [45]. Depending on the stoichiometry and reaction conditions, either mono- or bis- $\mu_{3}$-alkynylGroup 11 metal cluster compounds may be obtained. In some cases, further reaction may occur to give bi-, tetra- or hexa-nuclear clusters.[41,48]

## ACCEPTED MANUSCRIPT

We considered that it would be interesting to determine whether any interaction between the end-groups would occur in similar systems in which two $-\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}\{\mathrm{Ru}(\mathrm{dppe}) \mathrm{Cp} *\}$ fragments (a strong electron donor) are linked by clusters $\mathrm{M}_{3}(\mu-$ $\mathrm{dppm})_{3}(\mathrm{M}=\mathrm{Cu}, \mathrm{Ag})$. Complexes of the general formula $\left[\left\{\mathrm{M}_{3}(\mu-\mathrm{dppm})_{3}\right\}\left\{\mu_{3}-\right.\right.$ $\left.\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}[\mathrm{Ru}(\mathrm{dppe}) \mathrm{Cp} *]\}_{\mathrm{n}}\right] \mathrm{X}_{3-\mathrm{n}}\left(\mathrm{M}=\mathrm{Cu}, \mathrm{Ag} ; \mathrm{n}=1,2 ; \mathrm{X}=\mathrm{BF}_{4}, \mathrm{PF}_{6} ;\right.$ Scheme 1$)$ have now been synthesised and characterised, including single crystal X-ray studies of the $\mathrm{n}=1(\mathrm{Cu}$, $\mathrm{Ag})$ and $2(\mathrm{Cu})$ members. Some studies were also carried out with the diyndiyl-rhenium systems $\left[\left\{\mathrm{M}_{3}(\mu-\mathrm{dppm})_{3}\right\}\left\{\mu_{3}-\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}\left[\operatorname{Re}(\mathrm{CO})_{3}\left(\mathrm{Bu}_{2}^{\mathrm{t}} \text {-bpy }\right)\right]\right\}_{2}\right] \mathrm{X}$ with a view to determining any factors which may be responsible for the asymmetry found in the attachment of a diynyl group to the $\mathrm{M}_{3}$ clusters in some complex structures.

## 2. Results and discussion

### 2.1. Ruthenium complexes.

2.1.1. Synthesis and Spectroscopy. Bright orange crystalline $\left[\left\{\mathrm{Cu}_{3}(\mu-\mathrm{dppm})_{3}\right\}\left\{\mu_{3^{-}}\right.\right.$ $\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}[\mathrm{Ru}(\mathrm{dppe}) \mathrm{Cp} *]\}] \mathrm{X}_{2}[6] \mathrm{X}_{2}$ was obtained from $[\mathrm{Ru}(\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{CH})(\mathrm{dppe}) \mathrm{Cp} *]$ and $\left[\mathrm{Cu}_{2}(\mu-\mathrm{dppm})_{2}(\mathrm{NCMe})_{2}\right] \mathrm{X}_{2}[5-\mathrm{Cu}] \mathrm{X}_{2}$ in THF / $\mathrm{NEt}_{3}$ (Scheme 1; for comparative purposes, Scheme 1 shows the atom numbering scheme employed across the present compounds, as well as those derived from literature reports). Under similar conditions with $[\mathbf{5 - C u}]\left(\mathrm{PF}_{6}\right)_{2}$, attempts to add a second ruthenium diynyl fragment failed, only $[6]\left(\mathrm{PF}_{6}\right)_{2}$ being formed, even when a large excess of the diynyl complex was used. However, by using the stronger bases KOH or dbu (1,8-diazabicyclo[5.4.0]undec-1-ene), the bis-ruthenium complex $\left[\left\{\mathrm{Cu}_{3}(\mu-\right.\right.$ $\left.\mathrm{dppm})_{3}\right\}\left\{\mu_{3}-\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}[\mathrm{Ru}(\mathrm{dppe}) \mathrm{Cp} *]_{2}\right] \mathrm{PF}_{6}[7] \mathrm{PF}_{6}$ was formed, although in all cases small quantities of $[6]\left(\mathrm{PF}_{6}\right)_{2}$ were also obtained. Separation of the two complexes was readily achieved by column chromatography (alumina). The $\mathrm{BF}_{4}$ salts of $[6]^{2+}$ and $[7]^{+},[6]\left(\mathrm{BF}_{4}\right)_{2}$ and $[7] \mathrm{BF}_{4}$, were similarly obtained from $[\mathrm{Ru}(\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{CH})(\mathrm{dppe}) \mathrm{Cp} *]$ and $[5-\mathrm{Cu}]\left(\mathrm{BF}_{4}\right)_{2}$

Full characterization of these compounds from elemental microanalyses and by spectroscopy was achieved. The NMR spectra contain resonances as expected for the $\left\{\mathrm{Ru}(\mathrm{dppe}) \mathrm{Cp}^{*}\right\}$ and $\left\{\mathrm{M}_{3}(\mu \text {-dppm })_{3}\right\}$ fragments (Table 1$)$. The mono- and bis-diyndiyl complexes could be distinguished by the relative intensities of the dppe ( $\delta_{\mathrm{P}}$ ca 80 ) and dppm $\left[\delta_{\mathrm{P}}\right.$ ca $-7(\mathrm{Cu})$, ca -7 to $\left.+2(\mathrm{Ag})\right]$ resonances. The IR spectra of all complexes contain $v(\mathrm{C} \equiv \mathrm{C})$ bands at 1983 ( $\mathbf{6}$ and $\mathbf{8}$ ) or between 2015 and $2033 \mathrm{~cm}^{-1}$ ( $\mathbf{7}$ and $\mathbf{9}$ ); the $\mathrm{PF}_{6}$ and $\mathrm{BF}_{4}$ salts are distinguished by IR bands at 838 and $1052 \mathrm{~cm}^{-1}[\mathrm{~V}(\mathrm{PF})$ and $v(\mathrm{BF})$, respectively].

## ACCEPTED MANUSCRIPT

In most cases, four resonances for the atoms of the $\mathrm{C}_{4}$ chain(s) were observed in the ${ }^{13} \mathrm{C}$ NMR spectra, although the anticipated couplings were not always resolved. In $[7]^{+}$, a triplet at $\delta 121\left(J_{\mathrm{CP}}=21 \mathrm{~Hz}\right]$ is assigned to $\mathrm{C}(1,8)$, although $J_{\mathrm{CP}}$ is not resolved in the similar signal at $\delta$ ca 123 in $[9]^{+}$. A significant down-field shift occurs for $\mathrm{C}(1)$ in $[6]^{2+}$, which resonates at $\delta 158\left[J_{\mathrm{CP}}=21 \mathrm{~Hz}\right]$. This is accompanied by a well-resolved septet at $\delta 68.12\left[J_{\mathrm{CP}}=17 \mathrm{~Hz}\right]$, coupling to the six dppm-P nuclei being found, thus allowing this signal to be assigned to $\mathrm{C}(4)$. In the Ag complexes, this resonance is found downfield at $\delta$ ca 51 . Resonances for $\mathrm{C}(2,3)$ [and for $\mathrm{C}(6,7)$ if present] cannot be assigned unequivocally, but are found at $\delta$ ca 90 96 and 117. In $[8] \mathrm{BF}_{4}$, the ${ }^{31} \mathrm{P}$ dppm resonance appears as a well-resolved septet with $J_{\text {PAg }}=$ 365.7 Hz .

At low exit-voltage ( 80 V ), the electrospray-ionisation mass spectrum (ESI-MS) of $[8]\left(\mathrm{BF}_{4}\right)_{2}$ contained $\left[\mathbf{8}^{2+}+\mathrm{BF}_{4}^{-}\right]^{+},[8]^{2+}$ and $\left[\mathrm{Ag}_{2}(\mathrm{dppm})_{2}\right]^{2+}$ at $\mathrm{m} / \mathrm{z} 2247,1080$ and 492, respectively, the compositions being confirmed by high resolution mass measurements. Further fragmentation occurs at a higher exit-voltage ( 150 V ), when ions corresponding to $\left[\mathrm{Ag}_{2}(\mathrm{dppm}) \mathrm{Ru}\left(\mathrm{C}_{4}\right)(\mathrm{dppe}) \mathrm{Cp}^{*} \boldsymbol{J}^{+} \quad(\mathrm{m} / \mathrm{z} \quad 1283), \quad\left[\mathrm{Ag}_{3}(\mathrm{dppm})_{2} \mathrm{Ru}\left(\mathrm{C}_{4}\right)(\mathrm{dppe}) \mathrm{Cp}{ }^{*}\right]^{2+} \quad\right.$ (888), $\left[\mathrm{Ag}(\mathrm{dppm})_{2}\right]^{+}(877)$ and $[\mathrm{Ag}(\mathrm{dppm})]^{+}(491)$ are also present.
2.1.2. Crystal Structures. The molecular structures of the complexes $[6]\left(\mathrm{BF}_{4}\right)_{2},[7]\left(\mathrm{PF}_{6}\right)$ and $[8]\left(\mathrm{BF}_{4}\right)_{2}$ (orthorhombic and triclinic)(all solvated) have been determined. That of $[7]\left(\mathrm{PF}_{6}\right)$ confirms the expected structure with the $-\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}[\mathrm{Ru}(\mathrm{dppe}) \mathrm{Cp} *]$ groups linked via the $\left\{\mathrm{Cu}_{3}(\mu \text {-dppm })_{3}\right\}$ moiety. The cation (Fig. 1) is nearly linear with some asymmetry in the attachment of one of the $-\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}\left[\mathrm{Ru}(\mathrm{dppe}) \mathrm{Cp}^{*}\right]$ groups (see below for further discussion). The coordination environment of the $\mathrm{Ru}(\mathrm{dppe}) \mathrm{Cp} *$ end groups is typical with the one group rotated along the $[\mathrm{Ru}]-\left\{\mathrm{Cu}_{3}(\mu-\mathrm{dppm})_{3}\right\}$ centroid- $[\mathrm{Ru}]$ axis by ca $90^{\circ}$ with respect to the other.

## ACCEPTED MANUSCRIPT

This appears to be a consequence of the disposition of the dppm ligands about the central $\left\{\mathrm{Cu}_{3}(\mu-\mathrm{dppm})_{3}\right\}$ cluster.

Fig. 1. A representation of the molecular structure of $\left[\left\{\mathrm{Cu}_{3}(\mu-\mathrm{dppm})_{3}\right\}\left\{\mu_{3^{-}}\right.\right.$ $\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}[\mathrm{Ru}($ dppe $\left.) \mathrm{Cp} *]\}_{2}\right] \mathrm{PF}_{6}[7] \mathrm{PF}_{6}$. Ellipsoids have been drawn at the $50 \%$ probability level with solvate molecules, the anion, hydrogen atoms and the phenyl carbons of the dppe and dppm ligands (except the ipso-carbons) omitted for clarity.

## ACCEPTED MANUSCRIPT

The structures of $[\mathbf{6 , 8}]\left(\mathrm{BF}_{4}\right)_{2} \cdot \mathrm{nS}$ are very similar, being isomorphous (orthorhombic), with cation $\mathbf{8}$ further exemplified in the more precise determination of the triclinic THF solvate of $[8]\left(\mathrm{BF}_{4}\right)_{2}$ [which offers more precise distances within the diynyl string (Table 2)] as presented in Fig. 2. The solvent contents of the lattices of orthorhombic $[\mathbf{6}, 8]\left(\mathrm{BF}_{4}\right)_{2}$, probably acetone, are ill-defined; for each of the four present structures a single formula unit, devoid of crystallographic symmetry, comprises the asymmetric unit. Comparative core geometries for the cations are given in Table 2. Fig. 2 presents representative plots of the cations of $[7]^{+}$and $[8]^{2+}$, in particular highlighting the disposition of the diynyl group(s) around the $\left\{\mathrm{M}_{3}(\mu-\mathrm{dppm})_{3}\right\}$ cluster.

Note in (a) the difference in bonding ( $\mu_{2}$ cf. $\mu_{3}$ ) of the two diynyl ligands [but an average of $\mathrm{C}(4)-\mathrm{Cu}$ and $\mathrm{C}(8)-\mathrm{Cu}$ in 7 gives 2.185 and $2.176 \AA$, respectively], and in (c) the interaction of the $\mathrm{BF}_{4}$ anion with the $\mathrm{Ag}_{3}$ cluster[absent in (b)]. In all structural projections, the unique dppmligands (see below) lie to the left of the figure, with their ' U ' methylene groups directed toward the reader in projection (i), and towards the quasi-mirror plane of the core in the plane of the page in (ii). Where phenyl and methylene hydrogen atoms are involved in close intramolecular contacts, these are shown.

Values of $E_{1}$ and $E_{2}$ are considerably larger than those of either $\left\{\mathrm{Ru}(\mathrm{dppe}) \mathrm{Cp}^{*}\right\}_{2}(\mu-$ $\left.C_{n}\right)(n=4,8)$, showing that insertion of the $M_{3}(d p p m)_{3}$ cluster makes the complexes generally more difficult to oxidise than analogues containing only carbon chains linking the two redox centres. While the separation of the first two waves $\left(\Delta E_{12}\right)$ is often considered to be an indication of the extent of interactions between the two redox centres, $[50,51]$ this assessment cannot be reliably made in the absence of other measurements. Several studies have shown that $\Delta E$ values are significantly affected by other factors, such as the medium used in the determination,[52] counter-ions present,[52,53] metal-metal electronic coupling (where closely spaced waves may result when the different oxidation states have similar stabilities),[53,54] conformational effects,[13c] and electrostatic and magnetic effects. This area has recently been reviewed.[52a,55-57]

Values of $\Delta E_{12}$ for [7] $\mathrm{BF}_{4}$ and [9] $\mathrm{BF}_{4}$ are 220 and 160 mV , respectively, i.e., they are within the cross-over area for Robin-Day Class II / Class III complexes, which is often considered to be around 200 mV .[50] These values are significantly lower than the values of 650 and 350 mV , respectively, for $\left\{\mathrm{Ru}(\mathrm{dppe}) \mathrm{Cp}^{*}\right\}_{2}\left(\mu-\mathrm{C}_{\mathrm{n}}\right)(\mathrm{n}=4,8)$ [41] and 380 mV for 4.[32] Thus, it may be concluded that the insertion of the trinuclear Group 11 cluster between the two diyndiyl fragments allows some electronic interaction between the metal termini to be maintained. More detailed studies, including spectroscopic methods, are necessary to delineate the reasons for these differences.
2.1.4. DFT calculations. In order to obtain some insight into possible reasons for these findings, density-functional theory (DFT) calculations have been carried out on the model cationic clusters $\left[\left\{\mathrm{M}_{3}(\mu-\mathrm{dHpm})_{3}\right\}\left\{\mu_{3}-\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}\left[\mathrm{Ru}(\mathrm{dHpe}) \mathrm{Cp}{ }^{*}\right]\right\}_{2}\right]^{+}\left(\mathrm{M}=\mathrm{Cu}[7-\mathrm{H}]^{+}, \mathrm{Ag}[9-\right.$ $\mathbf{H}]^{+}$) of $C_{s}$ symmetry where the dppm, dppe and $\mathrm{Cp}^{*}$ ligands have been replaced by the dHpm ,

## ACCEPTED MANUSCRIPT

dHpe and Cp ligands to reduce computational demands (see Experimental section for computational details).Results were compared and contrasted with those obtained for the mono-diynyl parent model compounds $\left[\left\{\mathrm{M}_{3}(\mu-\mathrm{dHpm})_{3}\right\}\left\{\mu_{3}-\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}[\mathrm{Ru}(\mathrm{dHpe}) \mathrm{Cp} *]\right\}\right]^{2+}(\mathrm{M}$ $\left.=\mathrm{Cu}[\mathbf{6}-\mathbf{H}]^{2+} \mathrm{Ag}[\mathbf{8}-\mathrm{H}]^{2+}\right)$.

Pertinent optimised metrical data are given in Table 2 for models $\mathbf{6 - H}, 7-\mathbf{H}$ and $\mathbf{8 - H}$ and compared to the experimental values. The agreement is moderately satisfactory probably due to the level of theory used ( $C_{s}$ symmetry imposed) as well as the relatively poor quality of some of the X-ray structures. Nevertheless, as observed experimentally a comparison between 6-H and $\mathbf{8 - H}$ for instance shows similar $\mathrm{Ru}-\mathrm{C}$ and $\mathrm{C}-\mathrm{C}$ bond lengths, but $\mathrm{C}-\mathrm{Cu}$ distances longer and more unsymmetrical in the bis-diynyl complex than in the mono-diynyl one. On the other hand, the $\mathrm{Cu}-\mathrm{Cu}$ contacts are on average shorter in the former than in the latter. Indeed, it has been shown that there are "soft" bonding interactions between the $\mathrm{d}^{10}$ metal centres in these systems, which results from a mixing of vacant $\mathrm{s} / \mathrm{p}$ orbitals into occupied d combinations [58,59] and / or dispersion forces.[58-61] This leads to some possible geometrical flexibility in the $\mathrm{M}_{3} \mathrm{C}_{2}$ core which can be readily influenced by crystal packing (compare the same compound within Pbca and $P \overline{1}$ symmetries in Table 2 for instance).

It was found that there are large energy gaps between the HOMO and the LUMO (of 2.32 eV and 2.29 eV for the $\mathrm{Cu}(\mathrm{I})$ and the $\mathrm{Ag}(\mathrm{I})$ complexes $[7-\mathrm{H}]^{+}$and $[9-\mathrm{H}]^{+}$, respectively (Fig. 3), for a count of 46 cluster valence electrons (cve). Smaller HOMO-LUMO gaps are computed for the related 44 -cve molecules ( 1.56 and 1.77 eV for $[\mathbf{6 - H}]^{2+}$ and $[\mathbf{8}-\mathbf{H}]^{2+}$, respectively). Furthermore, contour plots of the HOMO and $\mathrm{HOMO}-1$ orbitals of $[7-\mathbf{H}]^{+}$ (Fig. 4; similar results were obtained for $[\mathbf{9 - H}]^{+}$), which are almost degenerate in energy, show that these orbitals are delocalised over the entire $\mathrm{Ru}^{-} \mathrm{C}_{4}-\mathrm{Cu}_{3}-\mathrm{C}_{4}-\mathrm{Ru}$ chain with a substantial contribution of the central $\mathrm{Cu}_{3}$ triangle $\left(22 \% \mathrm{Ru}, 57 \% \mathrm{C} 8\right.$ and $13 \% \mathrm{Cu}_{3}$ for the

## ACCEPTED MANUSCRIPT

HOMO and $29 \% \mathrm{Ru}, 56 \% \mathrm{C} 8$ and $8 \% \mathrm{Cu}_{3}$ for the HOMO-1). This suggests that there should be some communication between the ruthenium end-groups across the $\mathrm{Cu}(\mathrm{I})$ and $\operatorname{Ag}(\mathrm{I})$ clusters, and that the two oxidation waves observed in the CVs of $[7] \mathrm{PF}_{6}$ and $[9] \mathrm{PF}_{6}$ correspond to loss of two electrons from the HOMO 49a" or the HOMO-1 48a" (singlet dication) or of one electron from both (triplet dication). Interestingly, the singlet and triplet states of $[7-\mathbf{H}]^{3+}$ are very close in energy ( $7 \mathrm{~kJ} \mathrm{~mol}^{-1}$ in favour of the former).

### 2.2. Rhenium complexes

Yam and coworkers have described reactions between $\left[\mathrm{M}_{2}(\mathrm{dppm})_{2}(\mathrm{NCMe})_{2}\right] \mathrm{X}_{2}$ and $\operatorname{Re}(\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{CH})(\mathrm{CO})_{3}(\mathrm{NN})$ under various conditions to give complexes of the types $\left[\mathrm{M}_{3}(\mathrm{dppm})_{3}\left\{\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}\left[\operatorname{Re}(\mathrm{CO})_{3}(\mathrm{NN})\right]\right\}_{2}\right] \mathrm{PF}_{6} \quad\left[\mathrm{M}=\mathrm{Cu}, \mathrm{NN}=\right.$ bpy, $\mathrm{Me}_{2}$-bpy (13), $\mathrm{Bu}_{2}^{\mathrm{t}}{ }_{2}$-bpy $\left.[10]^{+} ; \quad \mathrm{M}=\mathrm{Ag}, \mathrm{NN}=\operatorname{bpy}(14)\right][46 \mathrm{c}]$, and $\left[\mathrm{Ag}_{6}(\mathrm{dppm})_{4}\left\{\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}\left[\operatorname{Re}(\mathrm{CO})_{3}(\mathrm{NN})\right]\right\}\right]\left(\mathrm{PF}_{6}\right)_{2}$ $\left(\mathrm{NN}=\mathrm{Me}_{2}\right.$-bpy, $\mathrm{Bu}^{\mathrm{t}}{ }_{2}$-bpy $[12]^{2+}$, phen, $\mathrm{Br}_{2}$-phen) [48], several examples of which have been characterised by X-ray structural studies. While the $\mathrm{Cu}_{3}-\mathrm{Me}_{2}$-bpy derivative has the usual relatively symmetric attachment of the diynyl $\mathrm{C}(1)$ to the $\mathrm{Cu}_{3}$ cluster $[\mathrm{Cu}(1,2,3)-\mathrm{C}(1)=$ 2.064-2.290 $\AA$; the corresponding ones in $\mathbf{1 4}$ are between 2.082 and $2.316 \AA$, see Table 2], the $\mathrm{Ag}_{3}$-bpy analogue, which contains two different independent molecules display an unusual asymmetric arrangement of one of the diynyl carbons to the $\mathrm{Ag}_{3}$ cluster with $\mathrm{Ag}-\mathrm{C}$ distances ranging from 2.140 to $3.170 \AA$ ) [46c]. Although the X-ray determination is not very accurate (some C-C bond lengths are abnormally short), it turns out the difference in carbon-metal triangle bonding is puzzling.

$\left[\mathrm{M}_{3}(\mathrm{dppm})_{3}\left\{\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}\left[\operatorname{Re}(\mathrm{CO})_{3}(\mathrm{NN})\right\}_{2}\right] \mathrm{PF}_{6} \mathrm{M}=\mathrm{Cu}, \mathrm{Ag} ; 10 \mathrm{M}=\mathrm{Cu}, \mathrm{NN}=\mathrm{Bu}_{2}^{\mathrm{t}}-\mathrm{bpy}\right.$

Our overall interest in this type of molecule as indicated in this paper prompted us to search for any reasons for this difference between the Cu and Ag analogues. DFT calculations on models derived from 14 suggested that, without any constraint, the asymmetric form was considerably less stable than the symmetric form, regardless of the metal. In other words, the ethynyl carbon atom seems to prefer to bind to the three metal atoms in a rather symmetrical fashion. Consequently, we have carried out some further

## ACCEPTED MANUSCRIPT

studies of this system with complexes containing the $\mathrm{Bu}^{2}$-bpy ligand. No X-ray structure of the $\mathrm{Cu}_{3}$ derivative was reported by Yam et al. [46c].
2.2.1. Structural studies. The $\mathrm{Cu}_{3}$ complex $\left[\mathrm{Cu}_{3}(\mu-\mathrm{dppm})_{3}\left\{\mu_{3}-\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}\left[\operatorname{Re}(\mathrm{CO})_{3}\left(\mathrm{Bu}_{2}{ }_{2}-\right.\right.\right.\right.$ bpy) $\left.\left.\left.\}_{2}\right]\right\}\right] \mathrm{PF}_{6}[\mathbf{1 0}] \mathrm{PF}_{6}$ was readily prepared using the same approach as described by Yam and coworkers.[46c] The X-ray structure reveals the expected $\mathrm{Cu}_{3}$ cluster supporting two diynyl ligands, but in contrast to what is observed for $\mathbf{1 3}$ (where $\mathrm{NN}=\mathrm{Me}_{2}$-bpy), one of these is asymmetrically attached, with two $\mathrm{Cu}-\mathrm{C}(1)\left[\mathrm{C}\left(1^{\prime}\right)\right]$ distances of 2.088(9), 2.126(8) [2.029(8), $2.154(8)] \AA$, and one somewhat longer at 2.479(8) [2.324(8)] $\AA$ (Fig. 5, Table 4). The $\mathrm{Cu}-\mathrm{Cu}$ distances within the $\mathrm{Cu}_{3}(\mathrm{dppm})_{3}$ moiety are 2.6012(12), 2.7183(14) and 2.5539(13) $\AA$. This distortion is further evidenced by the $[\mathrm{Re}]-\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}$-[ $\mathrm{Cu}_{3}$-centroid] angles which are $157.6^{\circ}$ [144.2] ${ }^{\circ}$, for $\operatorname{Re}(1)$ and $\operatorname{Re}(2)$ respectively. The $\mathrm{P}-\mathrm{CH}_{2}-\mathrm{P}$ moiety of one dppm ligand is directed toward each Re centre with the P atoms of the third dppm close to the plane of the $\mathrm{Cu}_{3}$ moiety [although the $\mathrm{CH}_{2}$ is directed toward $\mathrm{Re}(1)$ ]. Importantly, the cavity generated by the asymmetric attachment of the $\mathrm{Re}(2)$ end accommodates a fully occupied $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solvate molecule.

Fig. 5. $A$ representation of the molecular structure of $\left[\mathrm{Cu}_{3}(\mu-\mathrm{dppm})_{3}\left\{\mu_{3^{-}}\right.\right.$ $\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}\left[\operatorname{Re}(\mathrm{CO})_{3}\left(\mathrm{Bu}_{2}^{\mathrm{t}}\right.\right.$-bpy $\left.\left.\left.\left.\left.)\right]\right\}_{2}\right]\right\}\right] \mathrm{PF}_{6}[\mathbf{1 0}] \mathrm{PF}_{6}$ showing the solvate $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ molecule located between the $\mathrm{Cu}_{3}(\mathrm{dppm})_{3}$ cluster and the $\operatorname{Re}(\mathrm{CO})_{3}\left(\mathrm{Bu}_{2}^{\mathrm{t}}\right.$-bpy) capping moiety. Ellipsoids have been drawn at the $50 \%$ probability level with remaining solvate molecules, the anion, hydrogen atoms and the phenyl carbons of the dppm ligands (except the ipso-carbons) omitted for clarity.

* Bond lengths for both independent molecules are given, with the second showing more significant distortion.
$\dagger$ Due to a slightly different numbering format to the literature structures the atoms involved in the bonding under consideration are specified in
the Table.

## ACCEPTED MANUSCRIPT

The silver system proved to be more complex, the reaction between $\left[\mathrm{Ag}_{2}(\mu-\right.$ $\left.\mathrm{dppm})_{2}(\mathrm{NCMe})_{2}\right]\left(\mathrm{PF}_{6}\right)_{2}$ and $\operatorname{Re}(\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{CH})(\mathrm{CO})_{3}\left(\mathrm{Bu}_{2}^{\mathrm{t}}\right.$-bpy) being carried out in $\mathrm{MeOH} /$ $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and affording the mono-diynyl complex $\left[\mathrm{Ag}_{3}(\mu-\mathrm{dppm})_{3}(\mu-\mathrm{Cl})\left(\mu_{3}-\right.\right.$ $\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}\left[\operatorname{Re}(\mathrm{CO})_{3}\left(\mathrm{Bu}_{2}^{\mathrm{t}}{ }_{2}\right.\right.$-bpy $\left.\left.\left.\left.)\right]\right]\right\}\right] \mathrm{PF}_{6} \quad[11] \mathrm{PF}_{6}$, characterised by ESI-MS and a crystal structure (Fig. 6, Table 4). In contrast to the structure of the $\mathrm{Cu}_{3}$ complex above, however, there is a solvent molecule (refining as a disordered ethanol molecule) interacting with $\mathrm{Cl}(5 \mathrm{~A})$ and $\mathrm{Ag}(4)$ and causing the lengthening of the $\mathrm{Ag}(4) \ldots \mathrm{C}(4)$ separation to 2.383(4) $\AA$ $[\mathrm{Ag}(2,3)-\mathrm{C}(4) 2.250(4), 2.319(4) \AA]$. For comparison to $\mathrm{Cu}_{3}$ complex, the $[\mathrm{Re}]-\mathrm{C} \equiv \mathrm{CC} \equiv \boldsymbol{C}$ [ $\mathrm{Ag}_{3}$-centroid] angle is $173.0^{\circ}$, indicating a more symmetric arrangement of the Re centre of the face of the $\mathrm{Ag}_{3}$ complex. On the opposing face the Cl is disordered over two sites with a 0.8:0.2 ratio established by trial refinement; the major occupancy site $\mu_{2}-\mathrm{Cl}(5 \mathrm{~A})$ is coordinated by $\operatorname{Ag}(3)$ and $\operatorname{Ag}(4)$ [2.712(1) and 2.737(1) $\AA$ ] and hydrogen bonding to the ethanol solvate. The non-bonding $\mathrm{Ag}(2)-\mathrm{Cl}(5 \mathrm{~A})$ distance is $3.84 \AA$. The minor occupancy $\mu_{2}-\mathrm{Cl}(5 \mathrm{~B})$ is still asymmetrically bound but more centred with respect to the $\mathrm{Ag}_{3}(\mathrm{dppm})_{3}$ entity with bonding $\mathrm{Ag}(3)$ and $\mathrm{Ag}(4)$ distances of 2.894(5) and 2.890(6) $\AA$ and a non-bonding $\mathrm{Ag}(2)-\mathrm{Cl}(5 \mathrm{~B})$ distance of $3.20 \AA$.

Fig. 6. $A$ representation of the molecular structure of $\left[\operatorname{Ag}_{3}(\mu-\mathrm{dppm})_{3}\left(\mu_{2}-\mathrm{Cl}\right)\left\{\mu_{3}-\right.\right.$ $\left.\left.\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}\left[\operatorname{Re}(\mathrm{CO})_{3}\left(\mathrm{Bu}_{2}^{\mathrm{t}}-\mathrm{bpy}\right)\right]\right\}\right] \mathrm{PF}_{6} \quad[\mathbf{1 1}] \mathrm{PF}_{6}$. Ellipsoids have been drawn at the $50 \%$ probability level with solvate molecules, the anion, hydrogen atoms and the phenyl carbons of the dppm ligands (except the ipso-carbons) omitted for clarity. Only the major occupancy position (0.8) of the asymmetrically coordinated Cl ligand is shown.

## ACCEPTED MANUSCRIPT

We have been unable to obtain $\left[\mathrm{Ag}_{3}(\mathrm{dppm})_{3}\left\{\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}\left[\operatorname{Re}(\mathrm{CO})_{3}\left(\mathrm{Bu}_{2}{ }_{2}-\mathrm{bpy}\right)\right]\right\}_{2}\right] \mathrm{PF}_{6}$ to carry out a comparative structural determination; a minor product was identified as known $\left[\mathrm{Ag}_{3}(\mu-\mathrm{dppm})_{3} \mathrm{Cl}_{2}\right] \mathrm{PF}_{6}$ by ESI-MS and from an X-ray structure. This complex has the Cl ligands symmetrically coordinated to the $\mathrm{Ag}_{3}(\mathrm{dppm})_{3}$ entity (Table 4).

Further studies afforded the crystallographically characterised hexa-silver cluster $\left[\mathrm{Ag}_{6}(\mu-\mathrm{dppm})_{4}\left\{\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}\left[\operatorname{Re}(\mathrm{CO})_{3}\left(\mathrm{Bu}_{2}{ }_{2}-\mathrm{bpy}\right)\right]\right\}_{4}\right]\left(\mathrm{PF}_{6}\right)_{2}[\mathbf{1 2}]\left(\mathrm{PF}_{6}\right)_{2}$, reported earlier by Yam et al. [48], and directly related to the analogous crystallographically characterised $\mathrm{Me}_{2}$-bpy derivative (see SI Figure 1 for representations of the structure). Due to the additional steric bulk of the $\mathrm{Bu}^{\mathrm{t}}{ }_{2}$-bpy ligands coordinated at Re , $\left[\mathrm{Ag}_{6}(\mu-\mathrm{dppm})_{4}\left\{\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}\left[\operatorname{Re}(\mathrm{CO})_{3}\left(\mathrm{Bu}^{\mathrm{t}}{ }^{-}\right.\right.\right.\right.$ bpy) $\left.]_{4}\right]\left(\mathrm{PF}_{6}\right)_{2}$ crystallises in a different space group but the cation has a very similar structure to that of the $\mathrm{Me}_{2}$-bpy derivative. The central $\mathrm{Ag}_{6}(\mathrm{dppm})_{4}$ cluster has a flattened tetrahedral arrangement of four Ag centres $(\mathrm{Ag} 5, \mathrm{Ag} 6, \mathrm{Ag} 7, \mathrm{Ag} 9)$ with Ag 8 and Ag 10 bonded along opposite edges to $\mathrm{Ag} 5 / \mathrm{Ag} 9$ and $\mathrm{Ag} 6 / \mathrm{Ag} 7$, respectively. The $\mathrm{Ag}-\mathrm{Ag}$ bond lengths are in the range $2.9174(12)-3.0291(11) \AA$ [one longer interaction, $3.2495(15) \AA$, exists between Ag 5 and Ag 9 as part of the distorted tetrahedron]; these are shorter than the sum of van der Waals radii for $\mathrm{Ag}(3.4 \AA)[50]$ and supportive of weak $\mathrm{Ag} \cdots \mathrm{Ag}$ interactions. Two dppm ligands coordinate both Ag 8 and Ag 10 , while one P donor contributes to the coordination environment of the central Ag atoms. Each butadiynyl group binds into the diamond-shaped faces within the $\mathrm{Ag}_{6}$ core and is coordinated to three silver atoms in a $\mu_{3}, \eta^{1}$-bridging mode [Ag-C distances in the range $2.207(10)-2.79(1) \AA$ ]. The four butadiynyl groups are capped at the other ends by the $\operatorname{Re}(\mathrm{CO})_{3}\left(\mathrm{Bu}^{\mathrm{t}}\right.$-bpy) moiety.

## 3. Conclusions

Syntheses of $\mathrm{Cu}(\mathrm{I})$ and $\operatorname{Ag}(\mathrm{I})$ diynyl-Ru complexes of general formula $\left[\left\{\mathrm{M}_{3}(\mu-\right.\right.$ dppm $\left.)_{3}\right\}\left\{\mu_{3}-\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}[\mathrm{Ru}(\mathrm{dppe}) \mathrm{Cp} *]_{\mathrm{n}}\right] \mathrm{X}_{3-\mathrm{n}}\left(\mathrm{M}=\mathrm{Cu}, \mathrm{n}=1[6] \mathrm{X}_{2}, 2[7] \mathrm{X} ; \mathrm{M}=\mathrm{Ag}, \mathrm{n}=1\right.$ $[8] \mathrm{X}_{2}, 2[9] \mathrm{X} ; \mathrm{X}=\mathrm{BF}_{4}, \mathrm{PF}_{6}$ ) were successfully achieved. Cyclic voltammetric studies supported by DFT calculations suggest that electronic interaction between the two ruthenium centres in $\left\{\mathrm{Ru}(\mathrm{dppe}) \mathrm{Cp}^{*}\right\}_{2}\left(\mu-\mathrm{C}_{8}\right)$ is significantly weakened when a trinuclear $\mathrm{Cu}(\mathrm{I})$ or a $\mathrm{Ag}(\mathrm{I})$ cluster is inserted into the carbon chain, resulting from considerably weaker overlap between the carbon chains and the $\mathrm{M}_{3}(\mu-\mathrm{dppm})_{3}$ cluster. The presence of one or two diynyl ligands exercises a significant influence over the geometry of the trinuclear cation core. With only one ligand, and a feebly bound or non-existent donor to the other face, agostic interactions between dppm hydrogen atoms and the $M_{3}$ core may produce unusual conformational changes in the dppm chelate rings, as discussed elsewhere.[62].

In the rhenium system, the complexes $\left[\mathrm{Cu}_{3}(\mu-\mathrm{dppm})_{3}\left\{\mu_{3}-\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}\left[\operatorname{Re}(\mathrm{CO})_{3}\left(\mathrm{Bu}_{2}{ }^{\mathrm{t}}-\right.\right.\right.\right.$ bpy $\left.)]\}_{2}\right] \mathrm{PF}_{6}[\mathbf{1 0}] \mathrm{PF}_{6},\left[\mathrm{Ag}_{3}(\mu-\mathrm{dppm})_{3}(\mathrm{Cl})\left\{\mu_{3}-\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}\left[\operatorname{Re}(\mathrm{CO})_{3}\left(\mathrm{Bu}_{2}^{\mathrm{t}}-\mathrm{bpy}\right)\right]\right\}\right] \mathrm{PF}_{6}[\mathbf{1 1}] \mathrm{PF}_{6}$ and $\left[\mathrm{Ag}_{6}(\mu-\mathrm{dppm})_{4}\left\{\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}\left[\operatorname{Re}(\mathrm{CO})_{3}\left(\mathrm{Bu}_{2}{ }_{2}-\mathrm{bpy}\right)\right]\right\}_{4}\right]\left(\mathrm{PF}_{6}\right)_{2}[\mathbf{1 2}]\left(\mathrm{PF}_{6}\right)_{2}$ have been obtained from $\mathbf{5}$ and $\operatorname{Re}(\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{CH})(\mathrm{CO})_{3}\left(\mathrm{Bu}^{\mathrm{t}}\right.$-bpy).[46c,48] As shown in Tables 2 and 4 , there are two shorter and one longer $\mathrm{M}-\mathrm{M}$ separations in the $\mathrm{M}_{3}$ clusters of the bis-diynyl complexes. We have drawn attention to the asymmetric diynyl ligand found in the crystal of the $\mathrm{Ag}_{3}$ complex above. Theoretical calculations suggest that this conformer is significantly unstable with reference to the symmetrical form. However, in the X-ray structure, there does not appear to be any other molecule within the coordination sphere of the $\mathrm{Ag}_{3}$ cluster which might be responsible for partial loosening of the diynyl- $\mathrm{Ag}_{3}$ bonding. This result further suggests that the $\mathrm{C}(1)-\mathrm{M}$ bond is relatively weak, ready displacement of one M atom occurring by

## ACCEPTED MANUSCRIPT

interaction with appropriate solvate molecule(s). We note that the $\mathrm{M}_{3}(\mathrm{dppm})_{3}$ cluster is resistant to dissociation under these conditions.

## 4. Experimental

4.1. General Experimental Details. All reactions were carried out under dry nitrogen, although normally no special precautions to exclude air were taken during subsequent workup. Common solvents were dried, distilled under nitrogen and degassed before use. Separations were carried out by preparative thin-layer chromatography on glass plates ( 20 x $20 \mathrm{~cm}^{2}$ ) coated with silica gel (Merck 60 GF254, 0.5 mm thick).

Instruments. IR spectra were obtained on a Bruker IFS28 FT-IR spectrometer. Spectra in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ were obtained using a 0.5 mm path-length solution cell with NaCl windows. Nujol mull spectra were obtained from samples mounted between NaCl discs. NMR spectra were recorded on a Varian Gemini 2000 instrument $\left({ }^{1} \mathrm{H}\right.$ at $300.145 \mathrm{MHz},{ }^{13} \mathrm{C}$ at $75.479 \mathrm{MHz},{ }^{31} \mathrm{P}$ at 121.501 MHz ). Samples were dissolved in $d_{6}$-acetone or $\mathrm{C}_{6} \mathrm{D}_{6}$ contained in 5 mm sample tubes. Chemical shifts are given in ppm relative to internal tetramethylsilane for ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra and external $85 \%$ aqueous $\mathrm{H}_{3} \mathrm{PO}_{4}$ for ${ }^{31} \mathrm{P}$ NMR spectra. UV-vis spectra were recorded on a Varian Cary 5 UV-Vis/NIR spectrometer. Electrospray-ionisation mass spectra (ESI-MS) were obtained with Fisons Platform II (low resolution) or Bruker MicroTOF (high resolution) instruments from samples dissolved in MeOH unless otherwise indicated. Solutions were injected via a 10 ml injection loop. Nitrogen was used as the drying and nebulising gas. Chemical aids to ionisation were used as required [63]. Electrochemical samples $(1 \mathrm{mM})$ were dissolved in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ containing $0.5 \mathrm{M}\left[\mathrm{NBu}_{4}\right] \mathrm{BF}_{4}$ as the supporting electrolyte. Cyclic voltammograms were recorded using a PAR model 263 apparatus, with a saturated calomel electrode and ferrocene as internal calibrant $\left(\mathrm{FeCp}_{2} /\left[\mathrm{FeCp}_{2}\right]^{+}=+0.46 \mathrm{~V}\right.$ vs

SCE). A 1 mm path-length cell was used with a Pt-mesh working electrode, Pt wire counter and pseudo-reference electrodes. Elemental analyses were by Campbell Microanalytical Laboratory, University of Otago, Dunedin, New Zealand.

Reagents. The compounds $\operatorname{Ru}(\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{CH})(\mathrm{dppe}) \mathrm{Cp}^{*},[64] \operatorname{Re}(\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{CH})(\mathrm{CO})_{3}\left(\mathrm{Bu}_{2}^{\mathrm{t}}\right.$-bpy $)$ [46] and $\left[\mathrm{M}_{2}(\mu-\mathrm{dppm})_{2}(\mathrm{MeCN})_{2}\right] \mathrm{X}_{2}\left(\mathrm{X}=\mathrm{BF}_{4}, \mathrm{PF}_{6}\right)$ [45b, 65-67] were prepared by standard literature methods. In the course of this work, some anomalies in the reported syntheses led us to reinvestigate the nature of some of the binuclear acetonitrile-solvated $\mathrm{Cu}(\mathrm{I})-\operatorname{and} \mathrm{Ag}(\mathrm{I})-$ dppm precursor complexes, which are described elsewhere [67].

### 4.2. Ruthenium complexes

(a) $\left[\left\{C u_{3}(\mu-d p p m)_{3}\left\{\mu_{3}-C \equiv C C \equiv C\left[R u(d p p e) C p^{*}\right]\right\}\right]\left(B F_{4}\right)_{2}[6]\left(B F_{4}\right)_{2} . \mathrm{LiBu}(0.11 \mathrm{~mL}\right.$ of a 2.5 $M$ solution in hexanes, 0.28 mmol ) was added rapidly to $\mathrm{Ru}(\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{CH})(\mathrm{dppe}) \mathrm{Cp}^{*}(96 \mathrm{mg}$, $0.14 \mathrm{mmol})$ in THF $(40 \mathrm{~mL})$ at $-20^{\circ} \mathrm{C}$. The yellow solution was warmed to r.t., solid $\left[\mathrm{Cu}_{2}(\mu-\right.$ $\left.\mathrm{dppm})_{2}(\mathrm{NCMe})_{2}\right]\left(\mathrm{BF}_{4}\right)_{2}(236.9 \mathrm{mg}, 0.21 \mathrm{mmol})$ was added and the reaction mixture was stirred for 24 h . Evaporation of the resulting orange solution and extraction of the residue with acetone was followed by concentration to ca 2 ml and addition to hexane ( 50 mL ). The orange precipitate was filtered off, washed with hexane and dried in air to give $\left[\left\{\mathrm{Cu}_{3}(\mu\right.\right.$ dppm $\left.)_{3}\left\{\mu_{3}-\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}[\mathrm{Ru}(\mathrm{dppe}) \mathrm{Cp} *]\right\}\right]\left(\mathrm{BF}_{4}\right)_{2} \quad[6]\left(\mathrm{BF}_{4}\right)_{2}(188 \mathrm{mg}, 61 \%)$. The X-ray sample was obtained from acetone. Anal. Calcd $\left(\mathrm{C}_{115} \mathrm{H}_{105} \mathrm{~B}_{2} \mathrm{Cu}_{3} \mathrm{~F}_{8} \mathrm{P}_{6} \mathrm{Ru}\right)$ : $\mathrm{C}, 62.78 ; \mathrm{H}, 4.81$. Found: C, 62.82; H, 4.70. IR (Nujol, $\left.\mathrm{cm}^{-1}\right): v(\mathrm{C} \equiv \mathrm{C}) 1978 .{ }^{1} \mathrm{H} \operatorname{NMR}\left(\mathrm{CDCl}_{3}\right): \delta 1.67(\mathrm{~s}$, $15 \mathrm{H}, \mathrm{Cp} *), 2.30-2.60\left(\mathrm{~m}, 4 \mathrm{H}\right.$, dppe- $\left.\mathrm{CH}_{2}\right), 3.09,3.37\left(2 \mathrm{x} \mathrm{m}, 6 \mathrm{H}, \mathrm{dppm}-\mathrm{CH}_{2}\right), 6.60-7.80(80 \mathrm{H}$, $\mathrm{Ph}) .{ }^{13} \mathrm{C}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta 10.9\left(\mathrm{~s}, \mathrm{C}_{5} \mathrm{Me}_{5}\right), 27.2\left(\mathrm{~s}, \mathrm{dppm}-\mathrm{CH}_{2}\right), 30.6\left(\mathrm{~m}\right.$, dppe- $\left.\mathrm{CH}_{2}\right), 65.6$ $[\mathrm{C}(4)], 94.1,116.8[\mathrm{C}(2,3)], 95.4\left(\mathrm{~s}, C_{5} \mathrm{Me}_{5}\right), 128.0-139.0(\mathrm{Ph}) .{ }^{31} \mathrm{P}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta-8.9(\mathrm{~s}$, dppm), 78.7 (s, dppe).
(b) $\left[\left\{\mathrm{Cu}_{3}(\mu-\mathrm{dppm})_{3}\left\{\mu_{3}-C \equiv C C \equiv C\left[R u(d p p e) C p^{*}\right]\right\}\right]\left(P F_{6}\right)_{2}[6]\left(P F_{6}\right)_{2}\right.$.
$\left[\mathrm{Cu}_{2}(\mu-\mathrm{dppm})_{2}\left(\mathrm{NCMe}_{4}\right)\right]\left(\mathrm{PF}_{6}\right)_{2}(100 \mathrm{mg}, 0.074 \mathrm{mmol})$ and $\mathrm{Ru}(\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{CH})(\mathrm{dppe}) \mathrm{Cp}^{*}(36$ $\mathrm{mg}, 0.052 \mathrm{mmol})$ were dried under vacuum before $4: 1 \mathrm{THF} / \mathrm{NEt}_{3}(10 \mathrm{~mL})$ was added and the solution heated under reflux for 1 h . The resulting suspension was left to cool to r.t. and the bright orange crystalline product was filtered and washed with diethyl ether to give $\left[\left\{\mathrm{Cu}_{3}(\mu-\mathrm{dppm})_{3}\right\}\left\{\mu_{3}-\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}[\mathrm{Ru}(\mathrm{dppe}) \mathrm{Cp} *]\right\}\right]\left(\mathrm{PF}_{6}\right)_{2}[6]\left(\mathrm{PF}_{6}\right)_{2}(85 \mathrm{mg}, 70 \%)$. Anal. Calcd $\left(\mathrm{C}_{115} \mathrm{H}_{105} \mathrm{Cu}_{3} \mathrm{~F}_{12} \mathrm{P}_{10} \mathrm{Ru}\right)$ : C, 59.63; H, 4.57; M (dication), 2026. Found: C, 59.69; H, 4.63. IR (Nujol, $\mathrm{cm}^{-1}$ ): $v(\mathrm{C} \equiv \mathrm{C}) 1983 \mathrm{~m} ; v(\mathrm{PF}) 839 \mathrm{~s} .{ }^{1} \mathrm{H}$ NMR (acetone- $\left.d_{6}\right): \delta 1.77(\mathrm{~s}, 15 \mathrm{H}, \mathrm{Cp} *), 2.57$, $2.89\left(2 \mathrm{~m}, 2 \times 2 \mathrm{H}\right.$, dppe- $\left.\mathrm{CH}_{2}\right), 3.50\left(\mathrm{~m}, 6 \mathrm{H}\right.$, dppm- $\left.\mathrm{CH}_{2}\right), 7.09-7.89(80 \mathrm{H}, \mathrm{Ph}) .{ }^{13} \mathrm{C}$ NMR (acetone- $d_{6}$ ): $10.9\left(\mathrm{~s}, \mathrm{C}_{5} \mathrm{Me}_{5}\right), 28.6\left(\mathrm{~m}, \mathrm{CH}_{2} \mathrm{CH}_{2}\right), 68.1$ [septet, ${ }^{2} J_{\mathrm{CP}}=17 \mathrm{~Hz}, \mathrm{C}(4)$ ], 90.6 , $117.8[\mathrm{C}(2,3)], 95.7\left(\mathrm{~s}, C_{5} \mathrm{Me}_{5}\right), 129.0-137.9(\mathrm{Ph}), 158.4\left[\mathrm{t},{ }^{2} J_{\mathrm{CP}}=21 \mathrm{~Hz}, \mathrm{C}(1)\right] .{ }^{31} \mathrm{P}$ NMR (acetone- $d_{6}$ ): $\delta-142.4$ (septet, $\mathrm{PF}_{6}$ ), $-7.8(\mathrm{~s}, 6 \mathrm{P}, \mathrm{dppm})$, 78.9 (s, 2P, dppe). ESI-MS $(\mathrm{m} / \mathrm{z})$ : $1013, \mathrm{M}^{2+}$.
(c) $\left[\left\{\mathrm{Ag}_{3}(\mu \text {-dppm })_{3}\right\}\left\{\mu_{3}-C \equiv C C \equiv C\left[R u(d p p e) C p^{*}\right]\right\}\right]\left(P F_{6}\right)_{2} \quad[8]\left(P F_{6}\right)_{2}$. Rapid addition of $\mathrm{LiBu}(0.08 \mathrm{~mL}$ of a 2.5 M solution in hexanes, 0.20 mmol ) to a solution of $\mathrm{Ru}(\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{CH})(\mathrm{dppe}) \mathrm{Cp}^{*}(68.4 \mathrm{mg}, 0.10 \mathrm{mmol})$ in THF $(40 \mathrm{~mL})$ at $-20^{\circ} \mathrm{C}$ was followed by warming to ambient temperature and addition of $\left[\mathrm{Ag}_{2}(\mu-\mathrm{dppm})_{2}(\mathrm{NCMe})_{2}\right]\left(\mathrm{BF}_{4}\right)_{2}(93.2 \mathrm{mg}$, 0.075 mmol ). After stirring over 24 h , solvent was removed from the resulting orange solution. Extraction of the residue with acetone, concentration to ca 2 mL and addition of hexane $(50 \mathrm{ml})$ afforded an orange precipitate, which was recrystallised from acetone to give $\left[\left\{\mathrm{Ag}_{3}(\mu-\mathrm{dppm})_{3}\right\}\left\{\mu_{3}-\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}[\mathrm{Ru}(\mathrm{dppe}) \mathrm{Cp} *]\right\}\right]\left(\mathrm{PF}_{6}\right)_{2} \quad[8]\left(\mathrm{PF}_{6}\right)_{2}, \quad$ identified by ESI-MS (dication at $\mathrm{m} / \mathrm{z}$ 1080).

### 4.3. Rhenium complexes

The reactions were generally carried out as described earlier,[46c] although the work-up procedure differed.
(a) $\quad\left[\mathrm{Cu}_{3}(\mathrm{dppm})_{3}\left\{C \equiv C C \equiv C\left[\operatorname{Re}(\mathrm{CO})_{3}\left(\mathrm{Bu}^{t}{ }_{2}-\mathrm{bpy}\right)\right\}_{2}\right] P F_{6} \quad[10] P F_{6}\right.$. A mixture of $\operatorname{Re}(\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{CH})(\mathrm{CO})_{3}\left(\mathrm{Bu}^{\mathrm{t}}{ }_{2}-\mathrm{bpy}\right)(15 \mathrm{mg}, 0.025 \mathrm{mmol})$ and $\left[\mathrm{Cu}_{2}(\mathrm{dppm})_{2}(\mathrm{NCMe})_{2}\right]\left(\mathrm{PF}_{6}\right)_{2}(25.5$ $\mathrm{mg}, 0.020 \mathrm{mmol})$ in acetone $(5 \mathrm{~mL})$ containing an excess of KOH was stirred at r.t. for 24 h . After removal of solvent, the residue was dissolved in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ / hexane (2/1) and separated on a basic alumina column. The first yellow band eluted with the same solvent mixture contained $\operatorname{Re}(\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{CH})(\mathrm{CO})_{3}\left(\mathrm{Bu}^{\mathrm{t}}{ }_{2}\right.$-bpy) $(2.3 \mathrm{mg}, 15 \%)$. A red band was eluted with $\mathrm{CH}_{2} \mathrm{Cl}_{2} /$ hexane (4/1) and contained $\left[\mathrm{Cu}_{3}(\mathrm{dppm})_{3}\left\{\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}\left[\operatorname{Re}(\mathrm{CO})_{3}\left(\mathrm{Bu}_{2}^{\mathrm{t}} \text {-bpy) }\right\}_{2}\right] \mathrm{PF}_{6}\right.\right.$ $[10] \mathrm{PF}_{6}(21 \mathrm{mg}, 61.5 \%)$, which was obtained as orange crystals $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2} /\right.$ hexane $)$. IR $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{cm}^{-1}\right): v(\mathrm{C} \equiv \mathrm{C}) 2136 \mathrm{vw}, 2074 \mathrm{w} ; v(\mathrm{CO}) 2074 \mathrm{~s}, 1905 \mathrm{~s}(\mathrm{br}) .{ }^{1} \mathrm{H}$ NMR ( $d_{6}$-acetone $):$ $\delta 1.49\left(\mathrm{~s}, 36 \mathrm{H}, 12 \mathrm{Me}^{2} \mathrm{Ma}^{\mathrm{t}}\right), 3.01,3.22(2 \mathrm{x} \mathrm{m}, 12 \mathrm{H}, 6 \mathrm{dppm}), 6.80-7.20(\mathrm{~m}, 60 \mathrm{H}, 12 \mathrm{Ph})$, $7.92\left(\mathrm{~d}, J_{\mathrm{HH}}=5.9 \mathrm{~Hz}, 4 \mathrm{H}\right.$, bpy $), 8.88(\mathrm{~s}, 4 \mathrm{H}, \mathrm{bpy}), 9.27\left(\mathrm{~d}, J_{\mathrm{HH}}=5.9 \mathrm{~Hz}, 4 \mathrm{H}\right.$, bpy $) .{ }^{13} \mathrm{C}$ NMR ( $d_{6}$-acetone): $\delta 27.3-27.8[\mathrm{~m}(\mathrm{br}), \mathrm{dppm}], 30.6(\mathrm{~s}, \mathrm{Me}), 36.5\left(\mathrm{~s}, C\right.$-Me), $68.1\left(\mathrm{~s}, \mathrm{C}_{\gamma}\right), 92.1$ (s, $\left.\mathrm{C}_{\beta}\right), 119.5\left(\mathrm{~s}, \mathrm{C}_{\alpha}\right), 122.2-164.8(\mathrm{~m}, \mathrm{Ph}+\mathrm{bpy}), 192.6,199.4(2 \mathrm{x} \mathrm{s}, \mathrm{CO}) .{ }^{31} \mathrm{P}$ NMR $\left(d_{6^{-}}\right.$ acetone): $\delta-9.1(\mathrm{~s}),-12.6[\mathrm{~s}(\mathrm{br})]$ (ratio $2 / 1, \mathrm{dppm}),-147.2\left(\mathrm{sept}, J_{\mathrm{PF}}=707 \mathrm{~Hz}, \mathrm{PF}_{6}\right)$.
(b) $\left[\mathrm{Ag}_{3}(\mathrm{dppm})_{3}(\mathrm{Cl})\left\{C \equiv C C \equiv C\left[\operatorname{Re}(\mathrm{CO})_{3}\left(\mathrm{Bu}^{t}{ }_{2}-\mathrm{bpy}\right)\right\}\right] P F_{6} \quad[11] P F_{6}\right.$. The solution of $\operatorname{Re}(\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{CH})(\mathrm{CO})_{3}\left(\mathrm{Bu}_{2}^{\mathrm{t}}-\mathrm{bpy}\right)(15 \mathrm{mg}, 0.025 \mathrm{mmol})$ and $\left[\mathrm{Ag}_{2}(\mathrm{dppm})_{2}(\mathrm{NCMe})_{2}\right]\left(\mathrm{PF}_{6}\right)_{2}(22.5$ $\mathrm{mg}, 0.02 \mathrm{mmol})$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{MeOH}(3 / 1)(7 \mathrm{~mL})$ containing an excess of KOH gradually changed colour from yellow to orange after stirring at r.t. for 24 h . Work-up as in (a) above afforded $\operatorname{Re}(\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{CH})(\mathrm{CO})_{3}\left(\mathrm{Bu}_{2}^{\mathrm{t}}\right.$-bpy) $(1.1 \mathrm{mg}, 7 \%)$, with an orange band eluted with acetone / hexane $(1 / 2)$ containing $\left[\mathrm{Ag}_{3}(\mathrm{dppm})_{3}(\mathrm{Cl})\left\{\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}\left[\operatorname{Re}(\mathrm{CO})_{3}\left(\mathrm{Bu}_{2}^{\mathrm{t}}-\mathrm{bpy}\right)\right\}\right] \mathrm{PF}_{6}\right.$ $[11] \mathrm{PF}_{6}(5.7 \mathrm{mg}, 10 \%)$, which formed orange crystals $\left(\mathrm{EtOH} / \mathrm{Et}_{2} \mathrm{O}\right)$. $\mathrm{IR}\left(\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{cm}^{-1}\right)$ : $v(\mathrm{C} \equiv \mathrm{C}) 2135 \mathrm{vw}, 2084 \mathrm{w} ; ~ v(\mathrm{CO}) 2008 \mathrm{~s}, 1908 \mathrm{~s}(\mathrm{br}) .{ }^{1} \mathrm{H}$ NMR ( $d_{6}$-acetone): $\delta 1.46(\mathrm{~s}, 18 \mathrm{H}$, Me), 2.79, $3.48(2 \times \mathrm{m}, \mathrm{dppm}), 7.00-7.45(\mathrm{~m}, 60 \mathrm{H}, \mathrm{Ph}), 7.87\left(\mathrm{~d}, J_{\mathrm{HH}}=5.9 \mathrm{~Hz}, 2 \mathrm{H}\right.$ of bpy),
$8.80\left(\mathrm{~s}, 2 \mathrm{H}\right.$ of bpy), $9.16\left(\mathrm{~d}, J_{\mathrm{HH}}=5.9 \mathrm{~Hz}, 2 \mathrm{H}\right.$ of bpy). ${ }^{13} \mathrm{C}$ NMR ( $d_{6}$-acetone): $\delta 26.4(\mathrm{~m}$, dppm), 30.5 ( $\mathrm{s}, \mathrm{Me}$ ), 36.5 (s, $C$-Me), 66.1 ( $\mathrm{s}, \mathrm{C}_{\gamma}$ ), 90.3 (s, $\mathrm{C}_{\beta}$ ) 118.9 (s, $\mathrm{C}_{\alpha}$ ), 127.2-164.8 (Ph and bpy), 192.2, 199.1 ( $2 \mathrm{x} \mathrm{s}, \mathrm{CO}$ ). ${ }^{31} \mathrm{P}$ NMR ( $d_{6}$-acetone): $\delta-2.5,-4.3$ ( $2 \mathrm{x} \mathrm{m}, \mathrm{dppm}$ ), -147.3 (sept, $\left.J_{\mathrm{PF}}=707 \mathrm{~Hz}, \mathrm{PF}_{6}\right)$. ESI-MS (MeCN / m/z): 2099.042, $\mathrm{M}^{+}(\mathrm{calcd} 2099.178)$, 1018.953, $\left[\mathrm{Ag}_{2} \mathrm{Cl}(\mathrm{dppm})_{2}\right]^{+}$(calcd 1019.018). A light yellow band, eluted with acetone / hexane (1/1), contained known $\left[\mathrm{Ag}_{3} \mathrm{Cl}_{2}(\mathrm{dppm})_{3}\right] \mathrm{PF}_{6}(5.5 \mathrm{mg}, 29 \%)$, identified by ESI-MS and from an Xray structure. ESI-MS (MeOH / m/z): 1546.913, $\mathrm{M}^{+}$(calcd 1547.011), 1018.967, $\left[\mathrm{Ag}_{2} \mathrm{Cl}(\mathrm{dppm})_{2}\right]^{+}(\operatorname{calcd} 1019.018)$.
(c) $\left[A g_{6}(\mu-d p p m)_{4}\left\{C \equiv C C \equiv C\left[\operatorname{Re}(C O)_{3}\left(B u^{t}{ }_{2}-b p y\right)\right\}_{4}\right]\left(P F_{6}\right)_{2}[12]\left(P F_{6}\right)_{2}\right.$. A similar reaction between $\operatorname{Re}(\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{CH})(\mathrm{CO})_{3}\left(\mathrm{Bu}_{2}^{\mathrm{t}}\right.$-bpy $) \quad(15 \quad \mathrm{mg}, \quad 0.025$ mmol) and $\left[\mathrm{Ag}_{2}(\mathrm{dppm})_{2}(\mathrm{NCMe})_{2}\right]\left(\mathrm{PF}_{6}\right)_{2}(25.5 \mathrm{mg}, 0.02 \mathrm{mmol})$ was carried out in THF / $\mathrm{NEt}_{3}(4 / 1)(10$ $\mathrm{mL})$ at r.t for 36 h . Work-up as above afforded $\operatorname{Re}(\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{CH})(\mathrm{CO})_{3}\left(\mathrm{Bu}_{2}^{\mathrm{t}}\right.$-bpy) $(2.1 \mathrm{mg}$, $10.5 \%)$ and yellow-orange $\left[\mathrm{Ag}_{6}(\mathrm{dppm})_{4}\left\{\mathrm{C} \equiv \mathrm{CC} \equiv \mathrm{C}\left[\operatorname{Re}(\mathrm{CO})_{3}\left(\mathrm{Bu}^{\mathrm{t}}{ }_{2}-\mathrm{bpy}\right)\right]\right\}_{4}\right]\left(\mathrm{PF}_{6}\right)_{2}[\mathbf{1 2}]\left(\mathrm{PF}_{6}\right)_{2}$ ( $2.9 \mathrm{mg}, 7.2 \%$ ), eluted with $\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{MeOH}(20 / 1)$ and obtained as orange crystals $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right.$ / $\mathrm{C}_{6} \mathrm{H}_{6}$ ). This complex was identified by X-ray crystallography.

### 4.4. Structure determinations

Full spheres of diffraction data were measured at ca 150 K using CCD area-detector instrumentation [data for $[\mathbf{1 2}]\left(\mathrm{PF}_{6}\right)_{2}$ ] were collected at 100 K on the MX1 beamline of the Australia Synchrotron, $\lambda=0.71073 \AA$ Å.[68]). All data were measured using monochromatic Mo- $K \alpha$ radiation, $\lambda=0.71073 \AA . N_{\text {tot }}$ reflections were merged to $N$ unique ( $R_{\text {int }}$ quoted) after 'empirical'/multiscan absorption correction (proprietary software) and used in the full matrix least squares refinements on $F^{2}, N_{\mathrm{o}}$ with $F>4 \sigma(F)$ being considered 'observed'. Anisotropic displacement parameter forms were refined for the non-hydrogen atoms; hydrogen atoms

## ACCEPTED MANUSCRIPT

were treated with a riding model [weights: $\left.\left(\sigma^{2}\left(F_{\mathrm{o}}\right)^{2}+(\mathrm{a} P)^{2}+(\mathrm{b} P)\right)^{-1} ; P=\left(F_{\mathrm{o}}{ }^{2}+2{F_{\mathrm{c}}}^{2}\right) / 3\right]$. Neutral atom complex scattering factors were used; computation used the SHELXL97 or SHELXL2014 programs [69]. Pertinent results are given above and in Figs. 1 and 2 (which unless otherwise stated show non-hydrogen atoms with $50 \%$ probability amplitude displacement ellipsoids and hydrogen atoms having arbitrary radii of $0.1 \AA$ ), and in Tables 2-
6. CIF data (excluding structure factor amplitudes) have been deposited with the Cambridge Crystallographic Data Centre. CCDC reference numbers: 812795 [6] $\left(\mathrm{BF}_{4}\right)_{2}, 812796$ $[8]\left(\mathrm{BF}_{4}\right)_{2}$ (acetone solvate), $913187[7] \mathrm{PF}_{6}, 913188 \quad[\mathbf{8}]\left(\mathrm{BF}_{4}\right)_{2}$ (THF solvate), 1435455 $[\mathbf{1 0}] \mathrm{PF}_{6}, 1435410[\mathbf{1 1}] \mathrm{PF}_{6}, 1436607[\mathbf{1 2}]\left(\mathrm{PF}_{6}\right)_{2}, 1435449\left[\mathrm{Ag}_{3}(\mu-\mathrm{dppm})_{3} \mathrm{Cl}_{2}\right] \mathrm{PF}_{6}$.

Variata. In the determinations of $[6]\left(\mathrm{BF}_{4}\right)_{2}$ and $[8]\left(\mathrm{BF}_{4}\right)_{2}$, voids diffusely occupied with solvent residues (acetone) were not susceptible to satisfactory modelling, their contribution being suppressed in the refinements by the use of the program SQUEEZE [70]. In the determination of $[\mathbf{8}]\left(\mathrm{BF}_{4}\right)_{2} \cdot 5 \mathrm{THF}$, one disordered THF solvate molecule was refined with isotropic displacement parameters and a total of eight restraints was used to maintain chemically sensible bond lengths and angles for the disordered components.

The structure of [7] $\mathrm{PF}_{6} \cdot$ 4acetone has large solvent accessible voids. Seven partially occupied acetone solvate molecules were located in the voids and refined isotropically with occupancies between 0.5 and 0.75 . Further residual electron density equating to a unit cell volume of $220 \AA^{3}$ contained further peaks which could not be satisfactorily modelled. The thermal ellipsoids for the $\mathrm{PF}_{6}$ anion are consistent with some disorder of the fluorine atoms on one face of the anion but a chemically sensible disorder model could not be refined. A total of 23 restraints was used in the refinement of the structure; 17 restraints were used to maintain chemically sensible bond lengths and angles for the acetone solvate molecules and F210 (part of the $\mathrm{PF}_{6}$ anion) was refined using an ISOR restraint.

## ACCEPTED MANUSCRIPT

In [10] $\mathrm{PF}_{6}$ structure, three $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solvate molecules were identified and refined with $1.0,0.75$ and 0.5 occupancies after trial refinement. Geometries were restrained to ideal values with SAME commands and ISOR restraints were applied to the C and Cl atoms of the 0.5 occupancy $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solvate molecule. The SQUEEZE routine of PLATON [70] was applied to the collected data, which resulted in reductions in $R_{1}$ and $w R_{2} . R_{1}, w R_{2}$ and GOF before SQUEEZE routine: $7.16 \%, 22.33 \%$ and 1.025 ; after SQUEEZE routine: $6.78 \%$, $18.56 \%$, and 1.067 .

For $[\mathbf{1 1}] \mathrm{PF}_{6}$, DFIX restraints were used to maintain chemically sensible bond lengths for the EtOH solvate molecule in close proximity to the $\mathrm{Ag}_{3}(\mathrm{dppm})_{3}$ entity. The $S Q U E E Z E$ routine of PLATON [70] was applied to the collected data, which resulted in reductions in $R_{1}$ and $w R_{2} . R_{1}, w R_{2}$ and GOF before SQUEEZE routine: $5.09 \%, 16.44 \%$, and 1.070 ; after SQUEEZE routine: $4.49 \%, 12.00 \%$, and 1.105 .

Crystals of $\left[\mathrm{Ag}_{3} \mathrm{Cl}_{2}(\mathrm{dppm})_{3}\right] \mathrm{PF}_{6}$ were small and relatively weakly diffracting. There is some disorder / large thermal parameters associated with a single Ph ring of a dppm molecule (C54-C59 and associated H atoms). The Ph ring in question is directed into a cavity formed by the dppm ligands of an adjacent complex. Attempts to model this disorder were unsuccessful.

Crystals of $[\mathbf{1 2}]\left(\mathrm{PF}_{6}\right)_{2}$ were weakly diffracting and required synchrotron radiation to achieve usable diffraction. The $\operatorname{Re}(C O)_{3}\left(\mathrm{Bu}^{\mathrm{t}}{ }_{2}\right.$-bpy) moiety containing $\operatorname{Re} 4$ shows some disorder / high thermal displacement and a number of larger residual electron density peaks are located about Re4. The N of a coordinated $\mathrm{Bu}^{\mathrm{t}}{ }_{2}$-bpy ligand and the C of a CO ligand bonded to Re4 were refined with isotropic displacement parameters. SAME instructions and DFIX restraints were employed in the refinement (40 restraints) to maintain chemically sensible bond lengths and angles for the $\operatorname{Re}(\mathrm{CO})_{3}\left(\mathrm{Bu}_{2}^{\mathrm{t}}\right.$-bpy) moiety containing $\operatorname{Re} 4$ and a $\mathrm{PF}_{6}$ anion. A number of $\mathrm{C}_{6} \mathrm{H}_{6}$ solvate molecules were located in the difference map and refined

## ACCEPTED MANUSCRIPT

at full or partial occupancy based on trial refinements (solvates with occupancies of $50 \%$ or less were refined with isotropic displacement parameters). The structure has large solventaccessible voids and the SQUEEZE routine of PLATON [70] was applied to the collected data.

### 4.5. Computational details

Density functional calculations were carried out using the Amsterdam density functional (ADF) program [71] developed by Baerends and co-workers [72]. The Vosko-Wilk-Nusair parametrisation [73] was used for the local density approximation (LDA) with gradient correction for exchange (Becke88) [74] and correlation (Perdew86) [75]. The numerical integration procedure applied for the calculations was that developed by teVelde et al. [76]. The atom electronic configurations [77] were described using the basis IV available in the ADF code, i.e., by a triple- $\zeta$ Slater-type orbital (STO) basis set for H 1 s , C 2 s and 2 p and P 3 s and 3 p augmented with a 3 d single- $\zeta$ polarisation function for C and P and with a 2 p single- $\zeta$ polarisation function for H . A triple- $\zeta$ STO basis set was also used for Cu 3 d and 4 s , for Ru 4 d and 5 s , for Ag 4 d and 5 s , augmented with a single- $\zeta 4$ p polarization function for Cu , and with a 5 p single- $\zeta$ polarization function for Ru and Ag . A frozen-core approximation was used to treat the core shells up to 1 s for $\mathrm{C}, 2 \mathrm{p}$ for $\mathrm{P}, 3 \mathrm{p}$ for $\mathrm{Cu}, 4 \mathrm{p}$ for Ru , and 4 p for Ag [72]. Geometries were optimized using the analytical gradient method implemented by Verluis and Ziegler [78]. Representation of the molecular orbitals was done using MOLEKEL4.1 [79].

## Supplementary Material

Structural representations for $[\mathbf{1 2}] \mathrm{PF}_{6}$.

## Acknowledgements

We thank the Australian Research Council (ARC) for support of this work and Johnson Matthey plc, Reading, UK for a generous loan of $\mathrm{RuCl}_{3} \cdot \mathrm{xH}_{2} \mathrm{O}$. These studies were facilitated by travel grants (ARC, Australia and CNRS, France).

## Graphical Abstract - Synopsis

Several complexes containing diyndiyl $-\mathrm{ML}_{\mathrm{n}}\left[\mathrm{ML}_{\mathrm{n}}=\mathrm{Ru}(\mathrm{dppe}) \mathrm{Cp}^{*}, \operatorname{Re}(\mathrm{CO})_{3}\left(\mathrm{Bu}^{\mathrm{t}}{ }_{2}\right.\right.$-bpy $\left.)\right]$ fragments bridged by $\mathrm{M}_{3}(\mathrm{dppm}) 3$ clusters $(\mathrm{M}=\mathrm{Cu}, \mathrm{Ag})$ have been obtained from $\mathrm{HC}_{4}\left[\mathrm{ML}_{n}\right]$ and $\left[\mathrm{M}_{2}(\mathrm{dppm})_{2}(\mathrm{NCMe})_{x}\right]^{2+}(\mathrm{x}=3,4)$ and structurally characterised. Electrochemical and DFT studies have shown that the $\mathrm{ML}_{\mathrm{n}}$ groups interact with each other through the $\mathrm{M}_{3}(\mathrm{dppm})_{3}$ cluster.

## ACCEPTED MANUSCRIPT

## Highlights

- Complexes containing $\mathrm{M}_{3}(\mathrm{dppm})_{3}$ clusters $(\mathrm{M}=\mathrm{Cu}, \mathrm{Ag})$ attached to one or two $\mathrm{ML}_{\mathrm{n}}$ fragments $\left[\mathrm{ML}_{\mathrm{n}}=\mathrm{Ru}(\mathrm{dppe}) \mathrm{Cp}^{*}, \operatorname{Re}(\mathrm{CO})_{3}\left(\mathrm{Bu}_{2}^{\mathrm{t}}\right.\right.$-bpy $\left.)\right]$ have been obtained
- Structural characterisation of several complexes has been achieved
- Electrochemical measurements suggest that the terminal $\mathrm{ML}_{\mathrm{n}}$ groups interact through the $\mathrm{M}_{3}(\mathrm{dppm})_{3}$ cluster
- DFT studies have also been carried out
