HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

3 Abstract: We report herein a detailed structure-properties relationship study of the first
4 examples of electron-rich 4-substituted spirobifluorenes, namely
5
6 4-phenyl-*N*-carbazole-spirobifluorene (**4-PhCz-SBF**) and
7
8 4-(3,4,5-trimethoxyphenyl)-spirobifluorene (**4-Ph(OMe)₃-SBF**) for organic electronic
9 applications. The incorporation of the electron-rich moieties in the *ortho* position of the biphenyl
10 linkage (position C4) induces unique properties, very different to those previously described in
11 the literature for this family of semiconductors. Both dyes can be readily synthesised, possess
12 high triplet energies, excellent thermal stability and their HOMO energy levels are highly
13 increased compared to other 4-substituted SBFs. We also provide in this work the first
14 rationalization of the peculiar fluorescence of 4-substituted SBFs. Finally, the present dyes have
15 been successfully incorporated as host in green and blue Phosphorescent Organic Light-Emitting
16 Diodes with high performance either for the green (EQE of 20.2%) or the blue colour (EQE of
17 9.6%). These performances are, to the best of our knowledge, among the highest reported to date
18 for 4-substituted SBF derivatives.

36 1. INTRODUCTION

37
38 For the last twenty years, organic semi-conductors constructed on the spirobifluorene (SBF)
39 scaffold have encountered a fantastic development for Organic Electronic applications such as
40 blue fluorescent emitter in Organic Light-Emitting Diodes (OLEDs),¹⁻²¹ or in organic solar
41 cells.²²⁻²⁷ The very high performances obtained with some SBF based semi-conductors have
42 hence turned spiroconfigured compounds as one of the most important family of compounds for
43 electronics. 2-Substituted SBFs (see carbons labelling in Chart 1) are in this context the most
44 developed class of SBF-based materials, the para linkage between the pendant substituent in
45 position 2 and the constituted phenyl ring of the fluorene ensuring a good delocalization of π -

electrons. However, more recently, the growing necessity to design organic host materials for blue phosphors in Phosphorescent OLEDs (PhOLEDs) has led to new generations of SBF based materials with a wide energy gap (ca 4 eV) and a high triplet energy (E_T). These key properties are the consequences of a restricted π -conjugation within these materials. Thus, SBF compounds substituted in the ortho position of the biphenyl linkage (position C4, see carbons labelling in Chart 1) have encountered a great interest. Indeed, in 4-substituted SBFs, there is, due to the *ortho* linkage, a strong steric congestion which leads to an efficient π -conjugation disruption between the fluorene and its C4 pendant substituent. Despite these very appealing properties, only few examples of 4-substituted SBFs as host materials for blue and green PhOLEDs have been reported to date. These molecules incorporate either pure hydrocarbon fragments such as a phenyl²⁸ or a spirobifluorene core²⁹⁻³¹ or electron accepting moieties such as pyridine,³² pyrimidine³³ or diphenylphosphine oxide.^{34, 35} Thus, and despite the π -conjugation disruption between the fluorene and its substituent in C4, it has been shown in these previous works that electron-withdrawing groups such as pyridine isomers or pyrimidine (Chart 1) can selectively decrease the LUMO energy levels (localized on the electron poor moiety and/or on the adjacent fluorene core) keeping nevertheless the HOMO energy level (localized on the SBF core) unaltered.^{32, 33} However, the opposite strategy, that is increasing the HOMO energy level of 4-substituted SBFs, has to the best of our knowledge never been explored.

Chart 1. Examples of 4-substituted SBFs previously reported in the literature.³²⁻³⁵

1
2
3 As it is known that the increase of HOMO energy levels through the incorporation of
4 phenylacridine,³⁶⁻³⁹ indoloacridine,⁴⁰⁻⁴² quinolinophenothiazine⁴³ or quinolinophenoxazine⁴⁴
5 moieties instead of a fluorene core has remarkable consequences on the device performance we
6 wish to report herein the first examples of 4-substituted SBF derivatives incorporating electron-
7 rich fragments, namely *N*-phenylcarbazole in **4-PhCz-SBF** and trimethoxyphenyl in
8 **4-Ph(OMe)₃-SBF**, Scheme 1. Through a detailed structure-properties relationship study with the
9 corresponding building blocks, namely 4-phenyl-spirobifluorene (**4-Ph-SBF**), spirobifluorene
10 (**SBF**), 1,2,3-trimethoxybenzene (**Ph(OMe)₃**) and *N*-phenyl-carbazole (**N-PhCz**), we highlight
11 herein the remarkable influence of the C4-substituent on the electronic properties. Both dyes can
12 be readily synthesised, possess high E_T , excellent thermal stability and their HOMO energy
13 levels are highly increased compared to other 4-substituted SBFs reported to date. In addition,
14 both dyes display very different fluorescence properties and we provide herein the first
15 rationalization of the peculiar fluorescence of 4-substituted SBFs. Finally, both **4-PhCz-SBF**
16 and **4-Ph(OMe)₃-SBF** have been successfully incorporated as host in green and blue PhOLEDs
17 displaying a high efficiency. Thus, the green and blue PhOLEDs using **4-Ph(OMe)₃-SBF** as host
18 display a high EQE of 20.2% and 9.6% respectively. These performances are, to the best of our
19 knowledge, among the highest reported to date for 4-substituted SBF derivatives and highlight
20 the efficiency of the present design strategy.

RESULTS AND DISCUSSIONS

Scheme 1. Synthesis of **4-Ph(OMe)₃-SBF** and of **4-PhCz-SBF**.

As shown in scheme 1, both molecules were readily synthesised by a Miyaura-Suzuki coupling between the key platform 4-bromo-9,9'-spirobi[fluorene] **4-Br-SBF** (synthesized from the 4-bromofluorenone derivative)³² and either 9-(4-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)phenyl)-9H-carbazole or 3,4,5-trimethoxyphenylboronic acid providing with high yield 9-(4-(9,9'-spirobi[fluorene]-4-yl)phenyl)-9H-carbazole (**4-PhCz-SBF**, yield: 75%) or 4-(3,4,5-trimethoxyphenyl)-9,9'-spirobi[fluorene] (**4-Ph(OMe)₃-SBF**, yield: 83%). This short and efficient synthetic approach allows a gram-scale preparation and purification, key feature for further device fabrication.

At this stage, the fine analyses of the ¹H NMR spectra of **4-Ph(OMe)₃-SBF** and **4-PhCz-SBF** can provide interesting information on the influence of the pendant substituent on the chemical shift of the hydrogen atoms of the fluorene. The complete assignments of all signals have been

performed by 2D NMR spectroscopy experiments (HMBC, HSQC, $^1\text{H}/^1\text{H}$ COSY, see SI). Thus, in the ^1H NMR spectrum of **4-Ph(OMe)₃-SBF**, the hydrogen atom H3 of the fluorene (see chart 1) in α position of the 3,4,5-trimethoxyphenyl linkage is detected at 7.21 ppm, that is identical to that of the model compound **4-Ph-SBF** ($\delta_{\text{H3}} = 7.21$ ppm), see ^1H NMR spectra in SI. Switching from a 3,4,5-trimethoxyphenyl moiety to a *N*-phenylcarbazole moiety in **4-PhCz-SBF** leads to a non-negligible deshielding of 0.15 ppm ($\delta_{\text{H3}} = 7.36$ ppm), highlighting the different influence of the C4 substituent on the hydrogens chemical shifts of the fluorene backbone. This feature can be correlated to the angle formed between the fluorene and its substituent (see below the X-Ray structures). Indeed, the wider the angle, the weaker the electronic effects on the chemical shifts of the hydrogen atoms. One can note that this effect decreases as the distance to the linkage increases ($\delta_{\text{H1}} = 6.65$ ppm for **4-Ph(OMe)₃-SBF**, 6.67 ppm for **4-Ph-SBF** and 6.73 ppm for **4-PhCz-SBF**).

Figure 1. TGA (left) and DSC curves (right) of **4-Ph(OMe)₃-SBF** (blue line) and of **4-PhCz-SBF** (red line).

1
2
3 The thermal properties of **4-Ph(OMe)₃-SBF** and of **4-PhCz-SBF** were investigated by
4 thermogravimetric analysis (TGA, figure 1 left) and differential scanning calorimetry (DSC,
5 figure 1 right). The decomposition temperatures, T_d , corresponding to 5% mass loss were
6 recorded at 268°C for **4-Ph(OMe)₃-SBF** and at 311°C for **4-PhCz-SBF**. The two compounds
7 appear therefore more stable than their constituted building blocks **SBF** (T_d : 234°C) and
8 **4-Ph-SBF** (T_d : 254°C)²⁸ and also more stable than other SBF compounds substituted in position
9 4 with pyridine isomers (T_d between 217 and 242°C).³² Moreover, as the mass loss appears total
10 around 340°C for **4-Ph(OMe)₃-SBF** and around 410°C for **4-PhCz-SBF**, we believe that the
11 sublimation occurs at these temperatures without a real decomposition of the compounds.³⁶

12
13
14
15
16
17
18
19
20
21
22
23
24
25 DSC measurements were performed for the two dyes between 20 to 230°C. At the first heating
26 curve (see SI), the two compounds present a sharp endothermic peak at 223°C (**4-Ph(OMe)₃-**
27 **SBF**) and at 206°C (**4-PhCz-SBF**), associated with the melting of the two compounds (T_m : 215
28 and 200°C respectively from the peak onset). When both liquids were cooled down at the same
29 rate from 230 to 20°C, no recrystallization occurs and the cooling leads to amorphous solids. At
30 the second heating curve (figure 1, right), a glass transition phenomenon was observed at 100°C
31 for **4-Ph(OMe)₃-SBF** and at 135°C for **4-PhCz-SBF** (T_g : 90°C and 127°C *resp.* from the peak
32 onset). As observed above for the T_d , the T_g of **4-PhCz-SBF** appears therefore significantly
33 higher than that of their building blocks **SBF** and **4-Ph-SBF**²⁸ and also higher than those of SBFs
34 substituted in C4 with pyridine and pyrimidine units (T_g of these compounds range between 76
35 and 92°C).^{32, 33} Thus, the bulkiness induced by the presence of the phenylcarbazole group leads
36 to excellent thermal properties, key feature for the further device lifetime. The T_g of **4-**
37 **Ph(OMe)₃-SBF** is lower, 90°C, but remains in the same range than that of the other dyes
38 exposed above. Finally, one can note that, contrary to **SBF** and **4-Ph-SBF** which both present a

crystallization transition at $T_c=135^\circ\text{C}$ (upon cooling) and at $T_c=115^\circ\text{C}$ (upon heating),²⁸ neither **4-Ph(OMe)₃-SBF** nor **4-PhCz-SBF** present any crystallization phenomena whatever the DSC cycles, which is highly beneficial for further devices incorporation.

Figure 2. Different views of molecular structures of **4-PhCz-SBF** (left) and of **4-Ph(OMe)₃-SBF** (right) obtained by X-Ray diffraction on single crystals

X-Ray data on single crystals of **4-PhCz-SBF** and **4-Ph(OMe)₃-SBF** are presented figure 2. Structures of **4-PhCz-SBF** and **4-Ph(OMe)₃-SBF**, respectively, reveal one molecule in the $P 2_1/n$ and $P 2_1/c$ space groups, respectively. Several important structural features need to be stressed. First, the angle between the plane of the fluorene and the one of its C4-substituent needs to be evaluated as it drives the electronic coupling between the two fragments. Thus, for **4-PhCz-SBF**, an angle of 45.4° is measured between the pendant phenyl ring (labelled 5) and the substituted phenyl ring of the fluorene (labelled 4), whereas the corresponding angle of **4-Ph(OMe)₃-SBF** is impressively larger, evaluated at 78.0° . Thus, despite a larger substituent attached, **4-PhCz-SBF** displays a smaller angle than that of **4-Ph(OMe)₃-SBF**. This finding indicates that the substitution pattern, *i.e. meta/para vs para*, of the pendant phenyl ring 5 has a stronger impact on the angle than the bulkiness of the substituent itself. This is an interesting feature to finely control in the future the fluorene-phenyl angle and hence the resulting electronic properties (see below).

1
2
3 Compared to unsubstituted **4-Ph-SBF** (fluorene/phenyl angle was measured at 51.2° for one
4 molecule and at 56.6° for the other; two molecules were indeed present in the asymmetric unit),²⁸
5 the fluorene/phenyl angle is slightly smaller for **4-PhCz-SBF** and much larger for
6 **4-Ph(OMe)₃-SBF**. As this angle drives the intensity of the π -conjugation between the fluorene
7 and the substituent, this signs herein a weaker (respectively higher) π -conjugation breaking
8 between the two π -systems (fluorene and phenyl) in **4-PhCz-SBF** (respectively
9 **4-Ph(OMe)₃-SBF**) than in **4-Ph-SBF**.

10
11
12
13
14
15
16
17
18
19
20 Another interesting and uncommon structural feature in 4-substituted SBFs is linked to the
21 deformation of the substituted fluorene moiety. Indeed, in the case of **4-PhCz-SBF**, one can note
22 a strong deformation of the substituted fluorene core, 11.2° between rings 3 and 4, whereas the
23 unsubstituted fluorene presents a small angle between rings 1 and 2 of 4.0°. This is a very rare
24 structural feature as the fluorene moiety due to its ring bridging has most of the time a flat and
25 undistorted structure. This clearly shows the significant impact of the C4-substitution on the
26 folding of the fluorene.⁴⁵ A high value was also reported for **4-Ph-SBF** with an angle between
27 ring 3 and ring 4 as high as 12.7°.²⁸ However, it is important to mention that it remains difficult
28 to perfectly rationalize these structural deformations since the substituted fluorene of
29 **4-Ph(OMe)₃-SBF** is almost flat (angle between ring 3 and ring 4 of 2.7° almost identical to that
30 of its non-substituted fluorene, *i.e.* 3.2°). This feature may be assigned to the different
31 intermolecular packing observed for the two molecules (See SI). Indeed, in the packing diagram
32 of **4-PhCz-SBF**, short C/C intermolecular distances are observed ($d_{C/C} = 3.28$ and 3.32 Å, see
33 SI) between carbazole units and the unsubstituted fluorene unit (rings labeled 1 and 2). These
34 distances are shorter than the sum of the van der Waals radii⁴⁶ and translate significant
35 intermolecular interactions between **4-PhCz-SBF** molecules in the solid state. In addition, some
36
37
38
39
40
41
42

49
50
51
52
53
54
55
56
57
58
59
60

short C/H intermolecular distances are also detected ($d_{C/H} = 2.84\text{--}2.89 \text{ \AA}$, see SI), being slightly shorter than the sum of the van der Waals radii.⁴⁶ However, in the case of **4-Ph(OMe)₃-SBF**, no short C/C intermolecular contacts are observed in the packing diagram and only some short C/H intermolecular distances ($d_{C/H} = 2.64\text{--}2.88 \text{ \AA}$, see SI) between the fluorene units are detected. Finally, some short H/H and O/H intermolecular distances have also been measured ($d_{H/H} = 2.28 \text{ \AA}$, $d_{O/H} = 2.63 \text{ \AA}$, see SI). Thus, the very different molecular packing of the two compounds leads to different structural features such as the deformation of the fluorene and will also have interesting electronic consequences (See solid state emission below)

Figure 3. Cyclic voltammetry at 100 mVs^{-1} in $\text{CH}_2\text{Cl}_2/[\text{NBu}_4][\text{PF}_6]$ 0.2 M in the presence of **4-Ph-SBF** (black line), **4-PhCz-SBF** (red line), **N-PhCz** (red dotted line), **4-Ph(OMe)₃-SBF** (blue line) and **Ph(OMe)₃** (blue dotted line).

Electrochemical properties of the two compounds have been investigated by cyclic voltammetry (CV) recorded in CH_2Cl_2 both in reduction and in oxidation. Their electronic properties were compared to those (i) of **4-Ph-SBF** to shed light on the effect of electron donating fragments (methoxy and carbazole) and (ii) of their constituted building blocks, *N*-phenylcarbazole (**N-PhCz**) for **4-PhCz-SBF** and 1,2,3-trimethoxybenzene (**Ph(OMe)₃**) for **4-Ph(OMe)₃-SBF** in order to investigate the effect of their incorporation on the SBF core.

1
2
3 First, in reduction (figures in SI), no wave was detected in dichloromethane and the LUMO
4 energy levels of the two compounds were determined from the onset reduction potentials
5 at -1.97 eV for **4-PhCz-SBF** and at -1.91 eV for **4-Ph(OMe)₃-SBF**, that means close to the
6 LUMO of **4-Ph-SBF** (-1.95).^{47*} Thus, compared to **4-Ph-SBF** one can note that the onset
7 potential of **4-Ph(OMe)₃-SBF** is slightly lower and that of **4-PhCz-SBF** significantly higher.
8 This in accordance with the theoretical calculations presented below (figure 5), which show for
9 **4-Ph(OMe)₃-SBF** a weak contribution of the phenyl ring in the LUMO distribution due to the
10 large fluorene/phenyl angle and a strong contribution of the phenyl ring for both **4-PhCz-SBF**
11 and **4-Ph-SBF** due to the small fluorene/phenyl angle. Thus, electrochemical measurements and
12 theoretical calculations show the same trend for the LUMO energy levels of the three
13 compounds: **4-PhCz-SBF** LUMO level < **4-Ph-SBF** LUMO level < **4-Ph(OMe)₃-SBF** LUMO
14 level (LUMO levels are respectively calculated in vacuum at -0.64, -0.47 and -0.46 eV, see SI).

31
32 In oxidation, both compounds present successive oxidation waves with peak potentials at 1.21,
33 1.64, 1.86 V for **4-PhCz-SBF** (figure 3-left, red line) and at 1.33, 1.72/1.80 (very close waves),
34 2.1 V for **4-Ph(OMe)₃-SBF** (figure 3-right, blue line). Compared to **4-Ph-SBF**, which first
35 oxidation is centred at 1.68 V (figure 3, black line), both **4-PhCz-SBF** and **4-Ph(OMe)₃-SBF** are
36 clearly more easily oxidized. Furthermore, compared to the oxidation of their respective donor
37 fragment, **N-PhCz** (figure 3-left, red dotted line) and **Ph(OMe)₃** (figure 3-right, blue dotted
38 line), the first oxidation of **4-PhCz-SBF** and **4-Ph(OMe)₃-SBF** is slightly shifted to less anodic
39 values (E^1_{ox} : 1.21 V vs 1.29 V for **4-PhCz-SBF** vs **N-PhCz** and E^1_{ox} : 1.33 V vs 1.37 V for **4-**

45
46
47
48
49
50

51
52
53 * It should be mentioned that, in DMF, well defined waves are obtained (see SI) with peak
54 potentials recorded at -2.44 V for **4-PhCz-SBF** (LUMO: -2.10 eV), -2.55 V for **4-Ph-SBF**
55 (LUMO: -2.00 eV) and -2.57 V for **4-Ph(OMe)₃-SBF** (LUMO: -1.98 eV). Thus, the same
56 potentials trend is obtained (see SI) both in DMF and in CH₂Cl₂.
57
58
59
60

1
2
3 **Ph(OMe)₃-SBF** vs **Ph(OMe)₃**). For both **4-PhCz-SBF** and **4-Ph(OMe)₃-SBF**, the first oxidation
4
5 is therefore assigned to the oxidation of the corresponding electron-rich moieties with a different
6
7 influence of the spirofluorene core due to the different conjugation disruption. Thus,
8
9 **4-Ph(OMe)₃-SBF** is only shifted by 40 mV compared to **Ph(OMe)₃** whereas **4-PhCz-SBF** is
10
11 anodically shifted by 80 mV compared to its constituted unit **N-PhCz**. This difference can be
12
13 again correlated to the fluorene/phenyl angle which is strongly larger in the case of **4-Ph(OMe)₃-**
14
15 **SBF** (78.0°) than in the case of **4-PhCz-SBF** (45.4°), therefore inducing a more intense
16
17 conjugation disruption between the fluorene and the pendant phenyl for the former.
18
19

20
21 The second and third oxidations occur at 1.64, 1.86 V for **4-PhCz-SBF** and at 1.72/1.80 V for
22
23 **4-Ph(OMe)₃-SBF**, that means in the same potential range than the two successive oxidations of
24
25 **4-Ph-SBF** (1.68 and 1.88 V) and have been assigned to the oxidation of the fluorene units.²
26
27 Additionally, differential pulse voltammetry (DPV, see figure in SI) recorded for each compound
28
29 showed a three successive 1e⁻/1e⁻/3e⁻ oxidations for **4-PhCz-SBF** and a four successive 1e⁻/1e⁻
30
31 /1e⁻/2e⁻ oxidation process for **4-Ph(OMe)₃-SBF**. Reaching the third oxidation process for
32
33 **4-PhCz-SBF** and the fourth one for **Ph(OMe)₃-SBF** lead to an electropolymerization process,
34
35 observed along successive CVs by the appearance and regular increase of new redox processes
36
37 (see figures in SI) and by the coating of the electrode surface by insoluble electroactive deposits.
38
39 The electrodeposition process, classically observed along oxidation of SBF derivatives, is
40
41 assigned to carbon-carbon coupling at the C2-C7 and C2'-C7' carbon atoms of the SBF units.²

⁴⁸⁻⁵¹ As no polymerization process was observed by oxidation of **Ph(OMe)₃**, the electrochemical
behaviour of the polymer obtained by anodic oxidation of **4-Ph(OMe)₃-SBF** is very similar to
that of **poly(4-Ph-SBF)**, both polymers possessing a HOMO level close to -5.5 eV (see figure in
SI). Contrariwise, as the anodic oxidation of **N-PhCz** at potential more positive than 2.2 V vs

1
2
3 SCE leads to the formation of an electroactive polymer (see figure in SI), the phenyl/carbazole
4 core is also surely involved in the electropolymerization process of **4-PhCz-SBF**. The HOMO
5
6 energy level of the corresponding polymer **poly(4-PhCz-SBF)** lies between that of **poly(N-**
7
8 **PhCz)**, -5.25 eV, and that of **poly(SBF)**, -5.57 eV.²⁸ A comparison of the electrochemical
9
10 behaviour of the polymers is presented in SI.
11
12
13

14
15 The HOMO energy levels of **4-PhCz-SBF** and **4-Ph(OMe)₃-SBF** determined from the onset
16 potential of their first oxidation (1.12 and 1.22 V respectively) lie at -5.52 eV and -5.62 eV,
17
18 respectively. Those HOMO energy levels are very close to those of their corresponding electron
19
20 donating fragment, **N-PhCz** (-5.59 eV) and **Ph(OMe)₃** (-5.67 eV), confirming the key
21
22 importance of these fragments on the HOMO energies. However, and as above mentioned, the
23
24 C4 substituted fluorene has a non-negligible influence on the HOMO energy levels as the
25
26 conjugation is not completely broken. In addition, the HOMO energy levels of both
27
28 **4-PhCz-SBF** and **4-Ph(OMe)₃-SBF** lie ca 0.3/0.45 eV higher than that of **4-Ph-SBF** (-5.95 eV)
29
30 due the electron-rich character of the carbazole or the methoxy group. Thus, due to the
31
32 conjugation disruption at the C4 position of **SBF**, the electrochemical data indicate that HOMOs
33
34 are mainly governed by the electron-rich building blocks with nevertheless an influence of the
35
36 **SBF** core. In case of **4-PhCz-SBF**, this fact is clearly confirmed by molecular modelling. Indeed,
37
38 the HOMO of **4-PhCz-SBF** is almost exclusively spread out on the *N*-phenylcarbazole fragment
39
40 (figure 5-left) whereas that of **4-Ph-SBF** on the **SBF** core (figure 5-right). **4-Ph(OMe)₃-SBF**
41
42 seems to be an intermediate case, with its HOMO delocalized both on **SBF** and **Ph(OMe)₃**
43
44 moieties (figure 5-middle). Depending on both the strength of the donor group and the
45
46 fluorene/phenyl angle, the HOMO (energy and shape) can hence be more or less governed by the
47
48 electron donating fragment. This particularity appears very interesting to finely tune the
49
50
51
52
53
54
55
56
57
58
59
60

electronic properties of 4-substituted SBFs. Finally, the electrochemical energy gaps ΔE^{el} of **4-PhCz-SBF** and **4-Ph(OMe)₃-SBF** are respectively evaluated at 3.55 eV and at 3.71 eV for **4-Ph(OMe)₃-SBF**, being shorter than that of **4-Ph-SBF** (4.0 eV) due to their strong increase of the HOMO energy level without significant modification of the LUMO energy levels.

Table 1. Electrochemical and spectroscopic properties of **4-PhCz-SBF** and **4-Ph(OMe)₃-SBF**.

1
2
3 should be mentioned that two other bands at higher energies (at ca 407, 421 nm) were detected
4 for **4-PhCz-SBF**, assigned through decay curves to fluorescence contributions, g. from the onset
5 of the last band in cyclohexane, h. $\lambda_{exc}=312$ nm
6
7

8 The UV-vis absorption spectra of the two compounds recorded in cyclohexane are presented
9
10 figure 4 (left). Both compounds present the same absorption band with a maximum at 309 nm
11
12 (molar absorption coefficient is higher in the case of **4-PhCz-SBF**) similar to the main
13 absorption band of **SBF** and of **4-Ph-SBF**. Hence, this band is due to transitions occurring on the
14
15 SBF unit. For **4-Ph(OMe)₃-SBF** and **4-Ph-SBF**, the contribution at 309 nm presents the same
16
17 wavelength tail at lower energy, leading to an optical gap ΔE^{opt} determined from the onset of the
18
19 absorption band of 3.82 eV. This tail translates a certain degree of conjugation between the
20
21 fluorene and its C4-substituent and it has been recently shown that it is possible to modify its
22
23 intensity by the nature of the substituent borne by the fluorene. Indeed, with pyridine isomers
24
25 attached (chart 1), this tail displays different intensities translating more or less longer π -
26
27 conjugated pathways.³² In the present case, the intensity of the tail (and hence the π -conjugation
28
29 between the phenyl and the fluorene) is almost identical between **4-Ph-SBF** and
30
31 **4-Ph(OMe)₃-SBF** clearly showing that the trimethoxy units have a very weak influence on the
32
33 absorption spectrum. This conjugation effect cannot be explored in the case of **4-PhCz-SBF**
34
35 because of the presence of (i) a shoulder at 325 nm and of (ii) an additional band at 340 nm. The
36
37 comparison of the spectrum of **4-PhCz-SBF** and the sum of spectra of each unit **4-Ph-SBF** and
38
39 **N-PhCz** (figure 4, right) shows a significant difference in the domain 295-330 nm. Indeed, in
40
41 that domain, **4-PhCz-SBF** displays higher absorption molar coefficients than the sum of its
42
43 building blocks. This feature indicates that the absorption of **4-PhCz-SBF** in the 295-330 nm
44
45 range is not only due to the sum of the absorption of **4-PhCz-SBF** and **N-PhCz** but is also
46
47 induced by the interactions between these two units. Thus, a charge transfer band between the *N*-
48
49
50
51
52
53
54
55
56
57
58
59
60

phenylcarbazole and phenyl-substituted SBF units is responsible of absorption in the 295-330 nm range leading to the shoulder at 325 nm and to the higher intensity of the band at 309 nm. Regarding the band at 340 nm, the difference between the spectrum of **4-PhCz-SBF** and the sum of the spectra of each constituted unit remains weak (figure 5, right). It should be noted that **4-Ph-SBF** has no absorption in this range whereas the absorption spectrum of **N-PhCz** (see SI) consists of three bands in the 290-350 nm range with maxima at 292, 327 and 339 nm. This comparison allows assigning for **4-PhCz-SBF** the band at 340 nm to the absorption of the *N*-phenylcarbazole fragment. The optical gap ΔE^{opt} of **4-PhCz-SBF**, 3.58 eV, has been determined from the onset of the absorption band at 340 nm.

Figure 4. Absorption spectra of **4-Ph-SBF** (black), **4-PhCz-SBF** (red), **4-Ph(OMe)₃-SBF** (blue) and the sum of the absorption spectra of **N-PhCz** and **4-Ph-SBF** (purple) in cyclohexane

In order to shed light on the origin of these bands, time-dependant density functional theory (TD-DFT) calculations have been performed with the 6-311+g(d,p) basis set using four different hybrid exchange-correlation functionals: B3LYP, PBE0, CAM-B3LYP and M06-2X. The B3LYP and PBE0 levels of theory give best matches in terms of wavelength range compared to CAM-B3LYP and M06-2X when looking at the band experimentally found at 309 nm (Table 2).

For all functionals, this band experimentally found at 309 nm is due to two transitions (λ_1 and λ_2 , Table 2)

Table 2. Calculated wavelengths corresponding to the band at 309 nm for **4-PhCz-SBF** and **4-Ph(OMe)₃-SBF** using the four different hybrid exchange-correlation functionals: B3LYP, PBE0, CAM-B3LYP and M06-2X

		B3LYP	PBE0	CAM-B3LYP	M06-2X
4-PhCz-SBF	λ_1 (nm)	304	295	267	268
	λ_2 (nm)	293	284	265	263
4-Ph(OMe)₃-SBF	λ_1 (nm)	299	289	268	267
	λ_2 (nm)	297	286	265	264

However, the charge transfer transition, experimentally found at 325 nm, is not well modeled by the B3LYP and PBE0 functionals. Indeed, according to the TD-DFT calculations obtained with these functionals, the charge transfer transition is found at a higher wavelength than the transition localized on the phenylcarbazole unit (experimentally found at 340 nm). By contrast, CAM-B3LYP and M06-2X functionals modelize a charge transfer transition at a lower wavelength than the transition localized on the phenylcarbazole unit. This finding is in agreement with what we experimentally observed as previously discussed (*i.e.* a charge transfer shoulder at 325 nm and a band at 340 nm localized on the phenylcarbazole part). For this reason, TD-DFT diagram (figure 5) obtained by M06-2X level of theory is shown despite the fact that the calculated transitions are underestimated by 50 nm.

Figure 5. Representation of the energy levels and the main molecular orbitals involved in the electronic transitions of **4-PhCz-SBF** (left), **4-Ph(OMe)₃-SBF** (middle) and **4-Ph-SBF** (right) obtained by TD-DFT M06-2X/6-311+G(d,p), shown with an isovalue of 0.04 [$e \text{ bohr}^{-3}$]^{1/2}. For clarity purpose, only the main contribution of each transition is shown (see SI for details).

In the case of **4-Ph(OMe)₃-SBF**, the HOMO is delocalized on the whole molecule (high coefficients on the SBF unit and weak coefficients on the C4 substituent). It is thus similar to the HOMO of **4-Ph-SBF** (delocalized on the SBF part, figure 5 right), with a small influence of the methoxy groups. The corresponding orbital delocalized on the SBF core in the case of **4-PhCz-SBF** is the H-1 orbital, since the HOMO is localized on the phenylcarbazole moiety. The LUMO of both compounds are delocalized on the C4 substituted fluorene unit and on the pendant phenyl ring, similarly to **4-Ph-SBF**. Likewise, the L+1 orbitals of the three compounds are delocalized on the non-substituted fluorene unit. A last orbital plays an important role in the case of **4-PhCz-SBF**, that is the L+2 orbital which is fully delocalized on the carbazole unit.

1
2
3 The main absorption band of **4-Ph(OMe)₃-SBF**, observed at 309 nm, has been attributed to
4 two π - π^* transitions, both from the HOMO (delocalized on the whole molecule) to the LUMO
5 (delocalized on the phenyl-fluorene unit) and L+1 orbital (delocalized on the unsubstituted
6 fluorene unit). **4-PhCz-SBF** displays the same band at 309 nm, which is due to the similar two
7 π - π^* transitions: both from the H-1 orbital (delocalized on the SBF core) to the LUMO
8 (delocalized on the phenyl-fluorene unit) and to the L+1 orbital (delocalized on the unsubstituted
9 fluorene unit). The attributions for both molecules are in perfect agreement with the previous
10 observation of a band due to transitions occurring on the SBF unit.
11
12

13 The shoulder at 325 nm of **4-PhCz-SBF** is due to a transition from the HOMO (delocalized on
14 the phenylcarbazole unit) to the LUMO (delocalized on the phenyl-fluorene unit) in accordance
15 with the previous hypothesis stating a band with a significant charge transfer character.
16
17

18 The band at 340 nm of **4-PhCz-SBF** is due to a transition from the HOMO to the L+2 orbital,
19 both localized on the phenylcarbazole unit, as expected by the presence of this band in the
20 absorption spectrum of its constituted building block **N-PhCz**. The apparent paradox of a higher
21 energy for the HOMO→LUMO transition than for HOMO→L+2 transition is due to an
22 inversion of the energy levels of the locally excited state and the charge transfer excited state
23 during the structural reorganizations of the excited states from the ground state geometry to the
24 corresponding relaxed geometries (see details in SI).
25
26

27 The HOMO→LUMO transition induces the band at 309 nm in the case of **4-Ph(OMe)₃-SBF**
28 and the band at 325 nm in the case of **4-PhCz-SBF**. Finally, the optical gaps ΔE^{opt} of **4-**
29 **Ph(OMe)₃-SBF** and **4-PhCz-SBF** respectively give us an evaluation of the difference between
30 the HOMO/LUMO and HOMO/L+2 orbitals respectively since these transitions are responsible
31 of the bands localized at low energy. Therefore the optical energy gap modulation between the

two compounds is 0.23 eV larger than the modulation between the energy gap obtained from electrochemical measurements (0.10 eV), which involve HOMO and LUMO.

Figure 6. Normalized emission spectra of **4-Ph-SBF** (black, $\lambda_{\text{exc}}=309$ nm), **4-PhCz-SBF** ($\lambda_{\text{exc}}=295$ nm, red), **4-Ph(OMe)₃-SBF** (blue, $\lambda_{\text{exc}}=309$ nm) and **N-PhCz** (pink, $\lambda_{\text{exc}}=280$ nm) recorded in cyclohexane, $A(\lambda_{\text{exc}}) < 0.1$

The fluorescence spectra of **4-PhCz-SBF**, **4-Ph(OMe)₃-SBF** and **4-Ph-SBF** recorded in cyclohexane are presented figure 6 (left). First, the fluorescence spectrum of **4-Ph(OMe)₃-SBF** is structureless and large ($\lambda = 375$ nm) and very similar to those previously reported for other 4-substituted SBFs.^{28-31, 35, 52, 53} In addition, the fluorescence spectrum of **4-Ph(OMe)₃-SBF** exactly displays the same shape than that of **4-Ph-SBF** but shifted by 17 nm ($\lambda = 359$ nm). Thus, both molecules possess a very large Stokes shift, which is one of the characteristics of the uncommon fluorescence of 4-substituted SBFs previously reported but still not understood to date.^{28-31, 35, 52, 53} We want to provide herein the beginning of an answer. We indeed believe that this large Stokes shift can be explained by the significant differences between the geometries of the ground (S₀) and first singlet excited (S₁) states observed for both **4-Ph(OMe)₃-SBF** (Figure 7-left) and **4-Ph-SBF** (Figure 7-right) through theoretical calculations. In addition, one can note

that the geometry difference between S0 and S1 is more pronounced for **4-Ph(OMe)₃-SBF** than for **4-Ph-SBF**, clearly explaining the difference observed in term of Stokes shift. Furthermore, this low rigidity (allowing an important rearrangement at the excited state) could be the reason of the large and unresolved fluorescence spectra of these two molecules. Thus, we believe that the very unusual fluorescence of 4-substituted SBFs finds its origin in this strong geometry difference between S0 and S1.

Figure 7. Superposition of the S0 (ground state) and S1 (first singlet excited state) molecular structures obtained by molecular modelling of **4-Ph(OMe)₃-SBF** (left, S0: sky blue, S1: green), **4-PhCz-SBF** (middle, S0: pink, S1: orange) and **4-Ph-SBF** (right, S0: grey, S1: black)

4-PhCz-SBF appears as a unique example in the 4-substituted SBFs family reported to date in the literature. Indeed, **4-PhCz-SBF** presents a well resolved emission spectrum with maxima at 345, 361 and a shoulder at 380 nm. The domain of emission wavelengths is similar to that of **4-Ph-SBF** (Figure 6-right). The structured shape is very similar to that of its constituted building block **N-PhCz** (which emits at 341 nm with a fine vibronic structure at 357 nm and a shoulder

1
2
3 around 375 nm, figure 6-right) but the ratio between the bands is different (1/1 for **4-PhCz-SBF**
4 and 3/2 for **N-PhCz**). In addition, the small Stokes-Shift of 5 nm, calculated from the difference
5 between the lowest energy absorption band (340 nm) and the highest energy emission band
6 (345 nm), is perfectly explained by the similar geometries of S0 and S1 (figure 7-middle). This is
7 a significant difference with **4-Ph(OMe)₃-SBF**, **4-Ph-SBF** and all the 4-substituted SBF reported
8 to date, which explained the different emission spectra of these molecules. Thus, the presence of
9 the pendant carbazole in **4-PhCz-SBF** has hence a key role in the peculiar fluorescence of
10 **4-PhCz-SBF**, by avoiding strong molecular rearrangements between S0 and S1. Indeed,
11 **4-PhCz-SBF** seems to have a high rigidity preventing reorganization at the excited state and this
12 high rigidity could also explain the highly structured fluorescence spectrum compared to the
13 other 4-substituted SBFs and notably **4-Ph(OMe)₃-SBF** and **4-Ph-SBF** presented above. This is
14 to the best of our knowledge the first rationalization of the peculiar fluorescence of this family of
15 dyes.

33
34 The quantum yield ϕ of **4-Ph(OMe)₃-SBF** was calculated in solution at 60% and that of
35 **4-PhCz-SBF** at 54% (reference : quinine sulphate). Both quantum yields are higher than those of
36 their constituted units ($\phi_{4-Ph-SBF}=40\%$, $\phi_{N-PhCz}=34\%$ and $\phi_{Ph(OMe)_3}<1\%$). It shows the strong
37 impact of the SBF core on the fluorescence quantum yield, especially in the case of
38 **4-Ph(OMe)₃-SBF**.

Figure 8. Left: Fluorescence decay curves of **4-PhCz-SBF** (red line) and **4-Ph(OMe)₃-SBF** (blue line) in cyclohexane ($\lambda_{\text{exc}} = 300$ nm, $\lambda_{\text{em}} = 375$ nm), right: solid state emission of **4-PhCz-SBF** (red line, $\lambda_{\text{exc}} = 280$ nm) and **4-Ph(OMe)₃-SBF** (blue line, $\lambda_{\text{exc}} = 280$ nm).

The fluorescence decays were recorded in cyclohexane and successfully fitted by single exponentials (figure 8-left) indicating a unique emission from the excited state S_1 to S_0 . The lifetime of **4-PhCz-SBF**, 4.0 ns, is close to that reported for **SBF** and **4-Ph-SBF** (4.6 and 4.2 ns, *resp.*²⁸) and shorter than that reported for **N-PhCz** (6.44 or 6.3 ns).^{54, 55} The lifetime of **4-Ph(OMe)₃-SBF** is shorter (2.8 ns) than those exposed above. For both **4-Ph(OMe)₃-SBF** and **4-PhCz-SBF**, the non-radiative rate constant (k_{nr}) was calculated at $1.4/1.2 \times 10^8$ s⁻¹ *resp.*, similar to those of **SBF** or **4-Ph-SBF** (1.3 or 1.4×10^8 s⁻¹). This shows that the substitution of the phenyl unit by three methoxy groups or by a carbazole unit does not allow additional non-radiative pathways of the excited state deactivation process. The radiative rate constant (k_r) of **4-Ph(OMe)₃-SBF** is however twice that of **4-PhCz-SBF** (2.1 vs 1.2×10^8 s⁻¹) and hence at the origin of the higher quantum yield of the former.

The solid state emission of **4-Ph(OMe)₃-SBF** ($\lambda_{\text{max}} = 378$ nm) is very similar to that of its solution spectrum with only a slight red shift of 3 nm (figure 8 right). Contrariwise, the emission spectrum of **4-PhCz-SBF** loses its resolution and appears red-shifted by ca 33 nm compare to

1
2
3 its solution spectrum. This may indicate strong interactions in the solid state, which can be
4 attributed to the phenyl-carbazole fragment in accordance with the short C/C distances observed
5 in the crystal packing (see above).
6
7
8
9

10 The triplet energies (E_T) were determined from the emission spectra at 77 K in 2-Me-THF
11 (Figure 9-top). Both **4-PhCz-SBF** and **4-Ph(OMe)₃-SBF** display a similar emission spectrum
12 with a first phosphorescence band recorded at 442 and 437 nm leading to E_T of 2.80 eV and 2.84
13 eV respectively. The E_T of both **4-Ph(OMe)₃-SBF** and **4-PhCz-SBF** are very similar to those of
14 **SBF** and **4-Ph-SBF** (2.87 and 2.77 eV *resp.*).²⁸ This is due to a similar localization of the triplet
15 exciton, delocalized on the substituted fluorene core with a weak contribution of the pendant
16 phenyl ring (Figure 9-bottom). This is very different to the HOMO and LUMO distribution, in
17 which the pendant phenyl ring has a significant contribution for both molecules (Figure 5). This
18 finding could be very useful to further tune the singlet and triplet energies of 4-substituted SBFs.
19 Phosphorescence decay was measured and the lifetime of the T1 state of **4-Ph(OMe)₃-SBF** and
20 **4-PhCz-SBF** was found to be very long, 4.6 and 4 s, respectively. Finally, both **4-Ph(OMe)₃-**
21 **SBF** and **4-PhCz-SBF** possess an E_T higher than that of the blue phosphor FIrpic (E_T : 2.62 eV)⁵⁶
22 being hence perfectly adapted to host it in optoelectronic devices.

Figure 9. Top: Emission spectra at 77 K in 2-Me-THF of **4-PhCz-SBF** (red line) and **4-Ph(OMe)₃-SBF** (blue line); bottom: Spin density distributions at the T1 state for **4-PhCz-SBF**, **4-Ph(OMe)₃-SBF** and **4-Ph-SBF** (isovalue of 0.004)

Green (dopant Ir(ppy)₃: tris[2-phenylpyridinato-C²,N]iridium(III)) and sky blue (dopant FIrpic: bis[2-(4,6-difluorophenyl)pyridinato-C²,N](picolinato)iridium(III)) PhOLEDs with **4-PhCz-SBF** or **4-Ph(OMe)₃-SBF** as the host were fabricated, characterised and their performances compared to that of other PhOLEDs using different 4-substituted-SBFs as host. The device architecture is given in the experimental part. In order to accurately compare the efficiency of the hosts in the device, we deliberately use the same PhOLED structure as that used in previous works.^{28, 32, 40} It should be also mentioned that the devices are fabricated without light extraction enhancement system and the phosphorescent emitters are not particularly oriented. We believe that a device optimisation with these specific hosts will lead to even further higher efficiencies.

Table 3. Green (Ir(ppy)₃) and blue (FIrpic) devices performances

	4-Ph(OMe)₃-SBF		4-PhCz-SBF	
dopant	Ir(ppy) ₃ 10%	FIrpic 20%	Ir(ppy) ₃ 10%	FIrpic 17%
V _{on} @L=1	4.3	4.2	3.7	3.75
CE (@J=1)	56.4	22.5	51.4	17.6
CE (@J=10)	43.3	19.7	44.7	16.5
CE _{max} (@ J=x)	78.0 (0.03)	24.2 (2.66)	67.9 (0.04)	18.0 (1.8)
PE (@J=1)	27.0	12.2	26.6	10.1
PE (@J=10)	16.6	8.2	17.9	7.5
PE _{max} (@ J=x)	48.1 (0.03)	13.9 (0.34)	45.4 (0.04)	11.0 (0.14)
EQE (@J=1)	14.6	8.9	13.2	6.5
EQE (@J=10)	11.2	7.8	11.5	6.1
EQE _{max} (@ J=x)	20.2 (0.03)	9.6 (2.66)	17.5 (0.04)	6.7 (1.8)

V_{on} (V); CE (cd/A); PE (lm/W); EQE (%); L (cd/m²); J (mA/cm²)

Green PhOLEDs (figure 10 and SI) with **4-PhCz-SBF** as the host present a high maximum External Quantum Efficiencies (EQE) reaching 17.5%. The corresponding Current Efficiency (CE) and Power Efficiency (PE) are recorded at 67.9 cd/A and 45.4 lm/W for **4-PhCz-SBF** (figure 10). Device based on **4-Ph(OMe)₃-SBF** displays higher performance in identical experimental conditions with a very high EQE of 20.2% and corresponding CE of 78.0 cd/A and PE of 48.1 lm/W for **4-Ph(OMe)₃-SBF** (figure 10). One can note that the turn-on voltage V_{on} (defined as the driving voltage to achieve the brightness of 1 cd/m²) of **4-Ph(OMe)₃-SBF** (4.3V) is higher than that of **4-PhCz-SBF** (3.7 V), translating a better charges injection in the former in accordance with the different energy gap of the molecules (Table 1). Finally, the electroluminescent spectra of both devices exclusively display the emission of the phosphor Ir(ppy)₃ in accordance with the emission of the pure Ir(ppy)₃.⁵⁷

Figure 10. Left: Normalized electroluminescent spectrum at 10 mA/cm² of the green devices using **4-PhCz-SBF** (red) or **4-Ph(OMe)₃-SBF** (blue) as host doped with Ir(ppy)₃ (10% in mass) as emitting layer; right: Current efficiency (CE, Cd/A, ×) and power efficiency (PE, lm/W, +) versus current density of the green devices using **4-PhCz-SBF** (red) or **4-Ph(OMe)₃-SBF** (blue) as host doped with Ir(ppy)₃ (10% in mass) as emitting layer.

Sky Blue PhOLEDs were also fabricated and characterized (figure 11 and SI). With **4-PhCz-SBF** as the host, the maximum EQE reaches 6.7% with corresponding CE and PE of 18.0 cd/A and 9.8 lm/W. As observed above for green devices, PhOLEDs based on **4-Ph(OMe)₃-SBF** display even higher performances with a maximum EQE as high as 9.6% with corresponding CE and PE of 24.2 cd/A and 12.0 lm/W. Similar conclusion than those exposed above can be drawn for Von. The EL spectra display exclusively the emission of the blue dopant at 474/498 nm for **4-Ph(OMe)₃-SBF** and 475/500 nm for **4-PhCz-SBF** in accordance with photoluminescence of pure Irpic film (475/500 nm).⁵⁶ The performance of **4-Ph(OMe)₃-SBF** is hence higher than those previously reported for 4-substituted SBF incorporating electron poor fragments.^{33,32} The hole carrier mobility of **4-PhCz-SBF** and **4-Ph(OMe)₃-SBF** have been finally determined by Space Charge Limited Current (SCLC) measurements. Thus, the hole mobility of **4-PhCz-SBF** and **4-Ph(OMe)₃-SBF** extracted from the Mott-Gurney law (see SI) is about 4.1×10^{-6} and

1.1×10^{-5} cm²/V.s respectively. The hole mobility of **4-Ph(OMe)₃-SBF** appears hence significantly higher than that of **4-PhCz-SBF**. This feature can be one of those involved in the higher PhOLEDs performance observed for **4-Ph(OMe)₃-SBF** compared to **4-PhCz-SBF**.

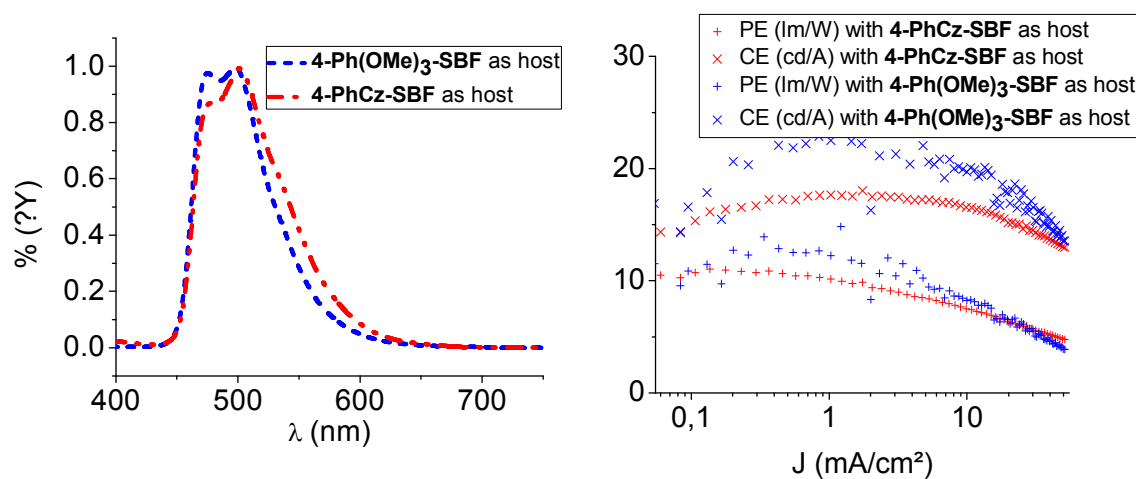

Figure 11. Left: Normalized electroluminescent spectrum at 10 mA/cm² of the blue devices using **4-PhCz-SBF** (red) or **4-Ph(OMe)₃-SBF** (blue) as host doped with FIrpic (17-20% in mass) as emitting layer; right: Current efficiency (CE, Cd/A, ×) and power efficiency (PE, lm/W, +) versus current density of the green devices using **4-PhCz-SBF** (red) or **4-Ph(OMe)₃-SBF** (blue) as host doped with FIrpic (17-20% in mass) as emitting layer

The performances of **4-Ph(OMe)₃-SBF** appear promising for a non-bipolar molecule. Indeed, the high performances are often obtained with molecules incorporating both electron-donating and electron-withdrawing fragments. Herein, with only an electron-donating unit, the corresponding devices display high performance, which could be surely further increased by device engineering or incorporation of an acceptor unit to decrease the LUMO energy level.

4. CONCLUSIONS

In summary, this work reports the first examples of electron-rich 4-substituted-SBFs, **4-PhCz-SBF** and **4-Ph(OMe)₃-SBF**, for green/blue PhOLED applications. Thanks to a detailed

1
2
3 structure-properties relationship study, this work shows that the incorporation of electron-rich
4 moieties in C4 of the SBF core induces unique properties, very different to those previously
5 reported for this family of molecules. Thus, the electronic properties of these dyes can be
6 modulated not only by the nature of the fragment borne by the SBF but also by the angle formed
7 between this fragment and the SBF moiety. Of particular interest, the structured emission of
8 **4-PhCz-SBF** with a short Stokes shift appears to be unique in the 4-substituted SBFs family. The
9 very similar geometry of its ground and first excited state appears herein as the first step in the
10 understanding of the peculiar fluorescence of 4-substituted SBFs. Due to their high E_T and high
11 HOMO energy levels, both **4-PhCz-SBF** and **4-Ph(OMe)₃-SBF** have been successfully
12 incorporated as host in green and blue PhOLEDs with high performance (EQE of 20.2% and
13 9.6% respectively) and low threshold voltages. These performances are, to the best of our
14 knowledge, among the highest reported to date for 4-substituted SBF derivatives, highlighting
15 the strong potential of **4-Ph(OMe)₃-SBF** (and more generally of the global approach) as host in
16 blue PhOLEDs. Bipolar hosts constructed on a similar design are currently developed in our
17 laboratories.
