Abstract:

Three monanionic gold dithiolene complexes with different exocyclic chalcogen atoms (O, S, Se) on the N-isopropyl-1,3-thiazoline-2-chalcogenone-4,5-dithiolate ligand, have been synthesized with the aim of modulating their properties. Due to the presence of the isopropyl (*iPr*) group in the plane of the thiazoline-2-chalcogenone ring, different *syn* and *anti* rotamers can exist, in solution and in the solid state. Characterization of these complexes by spectroscopic and electrochemical methods was carried out in order to investigate the influence of the size, electronegativity and polarizability of the exocyclic chalcogen atom. The molecular structure of the three anionic complexes $[\text{Au}(i\text{Pr-thiazYdt})_2]^{-1}$, with Y = O, S, Se, were established by single crystal X-ray diffraction studies. Theoretical calculations carried out at the DFT levels were realized on the three possible rotamers, *syn/syn*, *syn/anti* and *anti/anti* of the *trans*- $[\text{Au}(i\text{Pr-thiazYdt})_2]^{-1}$ complexes.

Keywords : dithiolene ligand; gold complex, rotamer, electrochemistry, X-ray diffraction

1. Introduction

When a molecule appears to be a promising precursor for the elaboration of conducting molecular materials, various chemical modifications of the precursor skeleton can be considered with the aim of a better understanding of the structure/property relationships.

For instance, after the discovery of the first organic metal from the association of tetrathiafulvalene (TTF) and tetracyanoquinodimethane (TCNQ), numerous modifications of the TTF moiety have been performed, particularly by replacing two or four sulfur atoms by selenium atoms [1]. Neutral radical gold bis(dithiolene) complexes are also promising systems for the elaboration of single component molecular conductors [2,3] and, within this framework, we recently reported complexes noted $[\text{Au}(\text{R-thiazdt})_2]^{\bullet}$ (R-thiazdt : N-alkyl-1,3-thiazoline-2-thione ring, Chart 1) where slight modifications performed on the dithiolene ligand skeleton play a crucial role in the observed properties [4,5].

Chart 1

In the case of the isopropyl group on the nitrogen atom (R = *i*Pr), we noticed in the organic precursors as well as in the gold complexes, the existence of different rotamers due to the orientation of the *i*Pr group relative to the plane of the thiazoline-2-thione ring [5]. Indeed, two stable conformations can be envisaged with the hydrogen atom of the *i*Pr group in the plane of the heterocyclic ring oriented towards the thione group or towards the substituent located at the 4-position of the heterocycle. These isomers are respectively noted *syn* and *anti* rotamers and are depicted in Chart 2 for the protected dithiolene ligand. Roussel *et al.* demonstrated long range conformational effects on this conformational equilibrium between the *syn* and *anti* rotamers induced by the substituents in positions 4 and 5 of the 3-isopropyl-4-alkyl-thiazoline-2-thione derivatives [6,7]. Furthermore, the nature of the substituent at the 2-position of the heterocycle can also play a role [8].

Chart 2

Thus, we postulated that larger or smaller atoms such as selenium or oxygen at the 2-position of the thiazoline core could also induce some modification on this *syn/anti* equilibrium.

Moreover, within the chalcogen group, the increase of the atomic radius follows an increase of polarizability together with a decrease in electronegativity. Both criteria can modify the overall properties of the monoanionic gold dithiolene species. Considering the importance of shape and size on the ability of a given complex to organize in the solid state in defined structures, we considered these modifications on the gold dithiolene complexes mentioned above and investigated accordingly the analogs of the monoanionic complex [Au(*i*Pr-thiazdt)₂] by replacing the exocyclic sulfur atom in the 2-position by either oxygen or selenium atoms. In order to facilitate the distinction between the three derivatives, we used a different notation [Au(*i*Pr-thiazYdt)₂] with Y = O, S, Se (Chart 3).

Chart 3

The preparation of the organic dithiolate ligand precursor as well as the corresponding anionic gold complexes will be described and the *i*Pr orientation will be investigated from a combination of variable temperature ¹H NMR, DFT calculations and X-ray crystal structure determinations.

2. Results and discussion

2. 1. Synthesis and characterization of the proligands

The protected dithiolate ligands **2**, **3** and **5**, with respectively Y = S, Se, O, were prepared starting from thiazoline-2-thione **1** [9] according to the chemical pathway depicted in Scheme 1. The bis-metallation of **1** with LDA followed by the addition of S₈ and bromopropionitrile led to **2** [5]. In order to generate the thiazoline-2-selone **3**, the exocyclic sulfur atom of the thiazoline-2-thione **2** was first alkylated with methyl iodide in refluxing acetone. Reaction with sodium hydroselenide afforded the protected dithiolate ligand **3** in 30% yield [10]. This strategy cannot be used for the preparation of the protected dithiolate ligand bearing a thiazoline-2-one core (Y = O). Indeed, the generation of a thiazoline-2-one from a thiomethyl salt implies the use of a basic reactant such as sodium methanolate which could also affect the cyanoethyl protecting group. Therefore, in order to avoid this unwanted deprotection, we performed the transformation into the thiazoline-2-one **4** on the unsubstituted N-*i*Pr-1,3-thiazoline-2-thione **1**. Its reaction with MeI in refluxing acetone affords the 2-methylthio-1,3-thiazolium salt which subsequently treated by NaOMe leads to the corresponding N-*i*Pr-1,3-thiazoline-2-thione **4** in 87 % yield. Thus, the protected dithiolate ligand **5** is obtained by using the same operating conditions as those used to form **2**.

Scheme 1.

Interestingly, two different behaviors can be observed on the room temperature ^1H NMR spectra of the five thiazoline derivatives **1-5**. For the precursors **1** and **4** which are not substituted on the 4 and 5 position of the thiazoline ring as well as for the protected dithiolate ligand **5** ($\text{Y} = \text{O}$), sharp signals are observed for the isopropyl group. Contrariwise, for the protected ligand **2** ($\text{Y} = \text{S}$) and **3** ($\text{Y} = \text{Se}$), broad signals for the isopropyl group are observed (Fig. 1). Thus, variable temperature ^1H NMR experiments were carried out on these two derivatives and the spectra recorded by decreasing the temperature by steps of 10 K are reported in Figure 1. Concerning the thiazoline-2-thione **2** which was previously reported [5], upon lowering the temperature, the broad signals decoalesce at 273 K into two doublets of approximately equal intensity for the methyl group (1.83 and 1.69 ppm) and into two septuplets with a similar ratio 48:52 (5.30 and 5.96 ppm) indicating the presence of the two rotamers in equal proportion (Chart 1). Similar investigations carried out on the protected dithiolate ligand **3**, with an exocyclic selenium atom, shows also a decoalescence of the signals observed at 273K, but with a slightly different evolution. Indeed, for **3** the signals decoalesce into two sets of signals corresponding to unequal rotamer populations (72:28). For instance, for the C-H two septuplets at 5.98 and 5.40 ppm with a ratio of 72:28 and for the methyl group two doublets at 1.66 and 1.88 ppm with a ratio of 72:28 are observed. This indicates the presence of two rotamers in different proportions.

Fig. 1. ^1H NMR spectra of the isopropyl group, C-H and CH_3 protons, of **2** ($\text{Y} = \text{S}$, left) and **3** ($\text{Y} = \text{Se}$, right) at various temperatures.

In their work on thiazoline-2-thione analogues, Roussel and Sandström [11] attributed the signals observed for the C-H at low field to the rotamer *anti*, due to the strong deshielding effect of the thiocarbonyl group. Accordingly, for **3** we assumed that the main isomer in solution was the rotamer *anti* (Chart 2). From this study, we also determined the free energy barriers between the *syn* and the *anti* forms which amounts to 14.5 (60 kJ.mol⁻¹) and 15.8 kcal.mol⁻¹ (66 kJ.mol⁻¹) for the proligands **2** (Y = S) and **3** (Y = Se) respectively. This difference can be attributed to the size of the chalcogen atom at the 2 position of the thiazoline ring. Indeed, the larger energy barrier for **3** can be ascribed to the steric hindrance generated by the larger exocyclic selenium atom.

As mentioned above, the room temperature ¹H NMR spectrum of the protected form **5** with an exocyclic oxygen atom shows only one set of signals for the methyl and the C-H groups. We also performed variable temperature experiments but this time by increasing the temperature by steps of 10 K. Up to 333 K no difference can be observed on the spectra indicating that no coalescence occurs. Thus in this case, either only one rotamer exists, or the smaller size of the oxygen atom does not impede the free rotation of the isopropyl group.

Fig. 2. ¹H NMR spectra of the isopropyl group, C-H and CH₃ protons, of **5** (Y = O) at various temperature.

In order to discriminate between these hypotheses, geometry optimizations were carried out on the two rotamers, *syn* and *anti*, for each proligands **2**, **3** and **5** [DFT-B3LYP/6-31G*]. In the three cases, the *syn* rotamer was found to have the lowest energy by 2.42 kcal/mol for Se, 0.57 kcal/mol for S and by 2.60 kcal/mol for O. These results indicate that the energy difference is more pronounced in the case of the proligands with either an exocyclic oxygen or selenium atom while for the sulfur derivative this difference is about four times smaller. This trend is in accordance with the experimental results obtained through the ^1H NMR investigations as for the sulfur derivatives upon lowering the temperature both rotamers were present in equal quantities while for the selenium one isomer is predominant (72%) and for the oxygen atom only one isomer is observed. Thus these calculations are in favor of the presence of one rotamer for the oxygen derivative. This is in agreement with the work of Sandström who observed that with N-*i*Pr-1,3-thiazolin-2-one and large substituent at the 4-position, the conformer *syn* was favored [11].

Another interesting aspect is to compare the frontier molecular orbitals energy for these proligands. As shown in Table 1, the energy of the HOMO and the LUMO of the exocyclic sulfur derivative, either *syn* or *anti* rotamer, lies in between those of the exocyclic oxygen and selenium derivatives. The effect of the exocyclic atom on the energy difference between the HOMO and LUMO may be noted. Indeed, the ΔE becomes smaller from the oxygen to the sulfur and selenium substitution. Accordingly a higher effect associated with electron delocalization is found with the selenium derivative.

Table 1 HOMO and LUMO levels in eV of the different rotamers of the proligands

	O Syn	O Anti	S Syn	S Anti	Se Syn	Se Anti
LUMO	-1.30	-1.38	-1.61	-1.72	-1.67	-1.74
HOMO	-6.178	-6.183	-5.83	-5.89	-5.50	-5.57
ΔE	4.878	4.803	4.22	4.17	3.83	3.83

2.2. Gold dithiolene complexes

The synthesis of the gold dithiolene complexes derived from the proligands **2**, **3** and **5** is depicted in Scheme 2. In order to prepare the monoanionic complexes, we first form the dithiolate ligand by adding sodium methanolate to a solution of the proligand. Addition of KAuCl_4 and PPh_4Cl to the medium yields the corresponding complexes (Scheme 2). Crystals of the three monoanionic gold complexes, $[\text{Ph}_4\text{P}][\text{Au}(\text{iPr-thiazYdt})_2]$, $\text{Y} = \text{O}, \text{S}, \text{Se}$, were obtained by slow concentration of acetonitrile solutions.

Scheme 2

All three complexes are isostructural, they crystallize in the monoclinic system, space group C2/c with the gold atom located on an inversion center. Selected bond distances and angles are collected in Table 2. The molecular structures of the monoanionic gold bis(dithiolene) complexes are shown in Figure 3. The coordination geometry around the gold ion is square planar. Interestingly, despite the number of possible isomers, all these gold dithiolene complexes exhibit a *trans* configuration as mostly observed for gold dithiolene complexes obtained with disymmetrically substituted dithiolene ligand [4,12-14], with only a few exceptions [4c,15]. Moreover, in the complexes with $\text{Y} = \text{S}$ and $\text{Y} = \text{Se}$, the rotamers *syn/syn* are observed in the solid state while for the complex with the exocyclic oxygen atoms, the *iPr* substituent is disordered on two positions indicating that the *syn* and *anti* isomers are present in the solid state. The metallacycles are not fully planar and the folding angle along the $\text{S}\cdots\text{S}$ axis increases slightly with the heavier chalcogens $\text{O}: 2.72(6)^\circ < \text{S}: 5.13(7)^\circ < \text{Se}:$

6.61(12)° (Table 2). This is in accordance with our previous observation on the N-Ethyl analogs $[\text{Au}(\text{Et-thiazYdt})_2]^{-1}$ (Y = O, S) where this folding angle along the S...S axis in the Et complex with Y = O was significantly smaller than in the Et complex with Y = S [4b].

Fig. 3. Molecular structures of (a) $[\text{Au}(\text{iPr-thiazOdt})_2]^{-1}$ apart de C-H of the *iPr* groups all the other hydrogen atoms have been omitted for clarity, (b) $[\text{Au}(\text{iPr-thiazSdt})_2]^{-1}$ et (c) $[\text{Au}(\text{iPr-thiazSedt})_2]^{-1}$ in $[\text{Ph}_4\text{P}][\text{Au}(\text{iPr-thiazYdt})_2]$ Y = O, S, Se.

Comparison of the bond lengths of the three monoanionic gold complexes shows that the exocyclic chalcogen atom has indeed an influence on the bond lengths of the thiazoline moiety. These modifications can be ascribed to the difference of

electronegativity/polarizability of the exocyclic chalcogen atom which is significantly transmitted to the heterocycle. Despite these modifications, the bond lengths of the metallacycles are quite comparable for the three complexes. Comparison of bond angles of the thiazoline-2-chalcogenone core shows some differences associated with the nature of the chalcogen atom indicating the release of strain due to the size of the exocyclic atom (Table 3). This can be also viewed on the non-bonded distance between S₁ and C₃ (*iPr*) which is the longest with the oxygen atom.

Y...C ₃ (<i>i</i> Pr)	2.901(5)	3.300(3)	3.412(8)

As observed for the protected ligands **2**, **3** and **5** the ¹H NMR spectra of the complexes [Au(*i*Pr-thiazYdt)₂]⁻¹ (Y = O, S, Se) recorded at room temperature show broad signals for the complexes with the two largest chalcogen atoms (Y = S, Se) and a well-defined spectrum with Y = O. Actually, the ¹H NMR spectrum of [Au(*i*Pr-thiazOdt)₂]⁻¹ displays two sharp doublets at 1.46 and 1.49 ppm with a ratio of 55:45 assigned to the CH₃ of the *i*Pr groups and a multiplet at 4.42 ppm resulting from the superposition of two septuplets of almost equal intensity (Fig. 4). Due to the presence of dissymmetrical ligands, all these complexes are susceptible to adopt a *trans* and *cis* configuration in solution. Based on the observation performed on proligand **5**, where we attributed the well-defined spectrum at room temperature to the presence of only one rotamer, the two sets of signals observed here at room temperature could be attributed to the coexistence of two diastereoisomers in solution, namely the *cis* and the *trans* isomers (chart 3).

Chart 3

Contrariwise, for the two other complexes $[\text{Au}(\text{iPr-thiazYdt})_2]^{-1}$ ($\text{Y} = \text{S}, \text{Se}$), two broad signals at 5.74 and 4.62 ppm of unequal intensity were observed for the C-H and a broad signal for the CH_3 of the *iPr* group. These broad signals indicate the existence of rotamers for these two complexes. For the $\text{Y} = \text{S}$ $[\text{Au}(\text{iPr-thiazSdt})_2]^{-1}$ complex, it was previously shown that upon lowering the temperature, the two broad signals for the C-H on the ^1H NMR spectra, with a ratio of 92:8 (5.74 and 4.62 ppm) decoalesce into two sharp multiplets resulting from the superposition of two septuplets due to the presence of possible six isomers in solution [5]. Variable temperature ^1H NMR experiments carried out on the $\text{Y} = \text{Se}$ $[\text{Au}(\text{iPr-thiazSedt})_2]^{-1}$ complex show one broad signal at 5.7 ppm for the C-H in favor of one rotamer in solution (Fig. 4). Upon lowering the temperature, one sharp septuplet is observed, indicating that in this case no *cis/trans* isomerism is observed.

Fig. 4. ^1H NMR spectra of the *iPr* group, C-H and CH_3 protons, of $[\text{Au}(\text{iPr-thiazOdt})_2]^{-1}$ (left) and $[\text{Au}(\text{iPr-thiazSedt})_2]^{-1}$ (right) at various temperature.

Redox properties Gold bis(dithiolene) complexes are electroactive species. To determine the redox behavior of $[\text{Au}(\text{iPr-thiazYdt})_2]^{-1}$ ($\text{Y} = \text{O}, \text{S}, \text{Se}$) species, we carried out cyclic voltammetry investigations, in dichloromethane in the presence of NBu_4PF_6 0.1 M as supporting electrolyte. The redox potentials are given in V vs SCE and are collected in Table 4 together with those of those of the N-Ethyl analogues $[\text{Au}(\text{Et-thiazYdt})_2]^{-1}$ for comparison purposes ($\text{Y} = \text{O}, \text{S}$) [4b]. Three different cyclic voltammograms (CV) were obtained as shown in Figure 5. For $[\text{Au}(\text{iPr-thiazYdt})_2]^{-1}$ ($\text{Y} = \text{O}, \text{S}$), upon anodic scan two oxidation processes are observed corresponding to the reversible oxidation of the monoanionic species into the neutral one and to the monocationic species. Surprisingly, the presence of exocyclic electronegative oxygen atoms increases the overall donating ability of the complex as the first oxidation potential of $[\text{Au}(\text{iPr-thiazOdt})_2]^{-1}$ occurs at 0.38 V while it is at 0.52 V for $[\text{Au}(\text{iPr-thiazSdt})_2]^{-1}$. Interestingly, the nature of the exocyclic atom influences also the potential domain of stability of the neutral species. Indeed the potential difference (ΔE) between the first and the second oxidation potential for $\text{Y} = \text{O}$ amounts to 470 mV while for $\text{Y} = \text{S}$ it is much smaller (110 mV). On the other hand, for $\text{Y} = \text{S}$ and $\text{Y} = \text{Se}$ the heteroatom does not modify significantly the first oxidation potential. On the CV of $[\text{PPh}_4][\text{Au}(\text{iPr-thiazSedt})_2]$ the redox processes are poorly defined due to adsorption phenomena at the electrode.

Fig. 5. Cyclic voltammograms of $[\text{PPh}_4][\text{Au}(\text{iPr-thiazOdt})_2]$ (left), $[\text{PPh}_4][\text{Au}(\text{iPr-thiazSdt})_2]$ (middle), $[\text{PPh}_4][\text{Au}(\text{iPr-thiazSedt})_2]$ (right) in CH_2Cl_2 , 0.1 M NBu_4PF_6 , Pt, SCE, $100 \text{ mV}\cdot\text{s}^{-1}$.

If we compare the redox potentials of the complexes bearing an ethyl or an isopropyl substituent on the nitrogen with the same outer chalcogen atom no modifications are observed. All these complexes exhibit on the cathodic scan an irreversible process attributed to the reduction of the monoanionic species into the dianionic complex. There again the nature of the outer chalcogen atom modifies the ease of reducing the complex and is consistent with the anodic behavior. The presence of the selenium atom facilitates the reduction while that of oxygen makes it more difficult. At first sight, the redox behavior of these complexes is in contrast with what would be expected if one considers only the electronegativity influence of the chalcogen atoms. However, this trend has also been noted on nickel dithiolene complexes $(\text{Bu}_4\text{N})_2[\text{Ni}(\text{dmit})_2]$ and $(\text{Bu}_4\text{N})_2[\text{Ni}(\text{dmid})_2]$ (dmit = 2-thioxo-1,3-dithiole-4,5-dithiolate and dmid = 2-oxo-1,3-dithiole-4,5-dithiolate) [16,17].

Absorption UV-vis-NIR spectroscopy: UV-vis-NIR investigations have been carried out on these complexes solubilized in dichloromethane ($C = 1.7 \cdot 10^{-5} \text{ M}$). These complexes exhibit absorption bands in the UV-vis region only and the data are gathered in Table 4. The absorption spectra of the three complexes display some similarities in the region 200-330 nm but with a main difference concerning the lowest energy absorption band (Fig. 6). Similar spectra have been obtained with other monanionic gold complexes [18,19]. On the spectra, it can be observed a significant influence of the outer chalcogen atom on the optical properties of the complexes especially on the absorption band observed at the lower energies. For instance, the value of this absorption band varies from 290 nm for the complex with oxygen atoms, to 360 nm for the one with sulfur atoms to reach 390 nm for the one with selenium atoms. Thus from the oxygen to the sulfur and the selenium atom the electronic delocalization on the ligand is increased. Attempts to analyze these complexes through spectroelectrochemical experiments were unsuccessful due to the adsorption of the neutral species at the electrode.

Fig. 6. UV-Vis spectra of $[\text{PPh}_4][\text{Au}(i\text{Pr-thiazYdt})_2]$ ($Y = \text{O}, \text{S}, \text{Se}$) in CH_2Cl_2 .

In order to better understand their structural, electrochemical and spectroscopic characteristics, density functional theoretical (DFT) calculations have been carried out on

these three complexes. They all can exist under the *cis* and *trans* configuration due to the presence of the dissymmetrical ligand, but since all the structures determined by X-ray crystallography are under the *trans* configuration, these calculations were performed only on the *trans* isomers. Geometry optimizations were carried out on the three possible rotamers for each *trans*-[Au(*i*Pr-thiazYdt)₂]⁻¹ complexes (Y = O, S, Se) using DFT calculations at the B3LYP/LanL2DZ level. All the optimized structures display a planar geometry around the gold atom unlike what was observed on the molecular structure determined by X-ray diffraction analysis. As an example, the optimized molecular structures of the three rotamers of the Y = O *trans*-[Au(*i*Pr-thiazOdt)₂]⁻¹ complex are represented in Figure 7.

Fig. 7 Optimized geometry for the 3 possible rotamers, *syn/syn*, *anti/syn* and *anti/anti*, calculated for the *trans*-[Au(*i*Pr-thiazOdt)₂]⁻¹ complex at the B3LYP/LanL2DZ level.

In the case of the *trans*-[Au(*i*Pr-thiazOdt)₂]⁻¹ complex, the most stable rotamer is the *syn/syn* rotamer. This rotamer is more stable than the *anti/syn* by 1.10 kcal/mol while the *anti/anti* is disfavored by 2.21 kcal/mol compared to the *syn/syn*. For the two other complexes, namely *trans*-[Au(*i*Pr-thiazSdt)₂]⁻¹ and *trans*-[Au(*i*Pr-thiazSedt)₂]⁻¹, the most stable rotamer is the

anti/anti conformer. The small energy difference between the most stable conformer, *anti/anti*, and the *syn/anti* one reaches 0.67 and 1.19 kcal/mol for the sulfur and the selenium complexes while it attains for the *syn/syn* 1.35 kcal/mol and 2.40 kcal/mol for the sulfur and the selenium complexes respectively. As observed for the proligand **2** (Y = S) the energy difference between the global minimum and the highest energy in *trans*-[Au(*i*Pr-thiazSdt)₂]⁻¹ complex is the smallest found in the series. A plausible interpretation for these observations would be that the thiocarbonyl and the sulfur alkyl chain at the 4-position exhibit a relatively close steric hindrance. It is worth noting that it does not correspond to the experimentally obtained structures from single X-ray diffraction analysis for both complexes *trans*-[Au(*i*Pr-thiazYdt)₂]⁻¹ (Y = S, Se). Actually, the presence of the tetraphenylphosphonium counter ion and solvent effects may contribute to this discrepancy between theoretical and experimental results.

Table 5 HOMO and LUMO levels in eV of the different rotamers of the *trans*-[Au(*i*Pr-thiazYdt)₂]⁻¹ complexes (Y = O, S, Se)

	<i>trans</i> -[Au(<i>i</i> Pr-thiazOdt) ₂] ⁻¹			<i>trans</i> -[Au(<i>i</i> Pr-thiazSdt) ₂] ⁻¹			<i>trans</i> -[Au(<i>i</i> Pr-thiazSedt) ₂] ⁻¹		
	<i>syn/syn</i>	<i>anti/syn</i>	<i>anti/anti</i>	<i>syn/syn</i>	<i>anti/syn</i>	<i>anti/anti</i>	<i>syn/syn</i>	<i>anti/syn</i>	<i>anti/anti</i>
LUMO	-1.10	-1.07	-1.05	-1.38	-1.36	-1.33	-1.41	-1.44	-1.38
HOMO	-2.36	-2.36	-2.36	-2.60	-2.60	-2.59	-2.60	-2.61	-2.59
ΔE	1.26	1.29	1.31	1.22	1.24	1.26	1.19	1.17	1.21

The calculated HOMO-LUMO gap, ΔE (Table 5) for the three *trans*-rotamers of the complexes follows the same trend as the one observed for the proligands above, that is the ΔE for the *trans*-[Au(*i*Pr-thiazSedt)₂]⁻¹ is the smallest one and the ΔE for the *trans*-[Au(*i*Pr-thiazOdt)₂]⁻¹ is the highest one in accordance with UV-vis spectroscopic investigations. The shift to higher energies of the HOMO and the LUMO for the *trans*-[Au(*i*Pr-thiazOdt)₂]⁻¹ complex compared to the sulfur and selenium analogs is in agreement with the

electrochemical investigations and the observed easier oxidation of this complex as well as the observed more difficult reduction of this complex.

3. Conclusions

In summary, a series of monoanionic gold dithiolene complexes with *i*Pr groups on the thiazole core of the ligand and with different exocyclic chalcogen atoms, $[\text{Au}(\textit{iPr}\text{-thiazYdt})_2]^{-1}$ ($\text{Y} = \text{O}, \text{S}, \text{Se}$) has been synthesized and studied. A combination of electrochemical, spectroscopic and structural data together with theoretical calculations have evidenced the influence of the nature of the outer chalcogen atom (O, S, Se) on the spectroscopic and redox properties of these complexes. Particularly, compared to sulfur and selenium, the exocyclic oxygen atom increases the potential domain of stability of the neutral radical species. Moreover the relative size of these chalcogen atoms and the steric hindrance generated influence the conformational equilibrium between the two preferred orientation of the *i*Pr against the thiazoline-2-chalcogenone ring, namely the *syn* and *trans* one. This study highlights how a simple change can tune the different properties of these gold dithiolene complexes.

4. Experimental Section

4.1. Materials and general methods

NMR spectra were recorded at room temperature using CDCl_3 unless otherwise noted.

Chemical shifts are reported in ppm and ^1H NMR spectra were referenced to residual CHCl_3 (7.26 ppm) and ^{13}C NMR spectra were referenced to CHCl_3 (77.2 ppm). Melting points were measured on a Kofler hot-stage apparatus and are uncorrected. Mass spectra were recorded

with Waters Q-ToF 2 instrument by the Centre Régional de Mesures Physiques de l'Ouest, Rennes. Elemental analyses were performed at the Centre Régional de Mesures Physiques de l'Ouest, Rennes. Column chromatography was performed using silica gel Merck 60 (70-260 mesh). CVs were carried out on a 10^{-3} M solution of complex in CH_2Cl_2 -[NBu₄][PF₆] 0.1 M. Potentials were measured *versus* Saturated Calomel Electrode (SCE). Chemicals and materials from commercial sources were used without further purification.

4.2. Synthesis and characterization

Bis(4,5-cyanoethylthio)-1,3-thiazoline-2-selone 3.

Under inert atmosphere, 1,3-thiazoline **2** (2.34 mmol, 0.77g) was dissolved in 15 mL of anhydrous acetonitrile. After the addition of iodomethane (2.92 mmol, 0.2 mL) the reaction mixture was stirred for 24 hours, under argon atmosphere, at 50°C. The medium was cooled at 0°C and acetonitrile was evaporated. The orange oil was used for the next reactions without other purification. ¹H NMR (300 MHz) δ 1.64 (d, 6H, CH₃, ³J_{HH} = 7.5 Hz), 2.1 (s, 3H, CH₃), 2.68 (t, 4H, CH₂, ³J_{HH} = 7.0 Hz), 3.04 (t, 4H, CH₂, ³J_{HH} = 7.0 Hz), 3.42 (t, 2H, CH₂, ³J_{HH} = 7.5 Hz), 4.8 (sept, 1H). Under inert atmosphere, sodium borohydride (0.19 g, 5.28 mmol) was dissolved in 20 ml of absolute ethanol. Selenium powder (4.68 mmol, 0.37 g) was added to the solution. The reaction medium was stirred until the formation of a homogeneous solution and the thiazolium salt (2.34 mmol) dissolved in 8 ml of anhydrous acetonitrile was added. After stirring 30 minutes, the solution was added to a 10% acetic acid solution. Ethanol and acetonitrile were evaporated and the medium was extracted with dichloromethane. The organic phase was washed with water and dried over MgSO₄. The resulting oil was purified by column chromatography on silica gel using $\text{CH}_2\text{Cl}_2/\text{Et}_2\text{O}$ (9.7/0.3) as eluent to afford the thiazoline-2-selone **3** as a yellow oil in 30% yield. $R_f = 0.63$ (SiO₂, $\text{CH}_2\text{Cl}_2/\text{Et}_2\text{O}$, 9.7/0.3). ¹H NMR (300 MHz) δ *rotamer anti* (72%): 1.66 (d, 6H, CH₃, ³J_{HH} = 7.1 Hz), 2.84 (t, 4H, CH₂,

$^3J_{\text{HH}} = 7.1$ Hz), 2.78 (t, 4H, CH₂, $^3J_{\text{HH}} = 7.1$ Hz), 5.98 (sept, 1H, CH, $^3J_{\text{HH}} = 7.1$ Hz); *rotamer syn* (28%): 1.88 (d, 6H, CH₃, $^3J_{\text{HH}} = 7.0$ Hz), 3.15 (t, 4H, CH₂, $^3J_{\text{HH}} = 7.0$ Hz), 3.25 (t, 4H, CH₂, $^3J_{\text{HH}} = 7.0$ Hz), 5.40 (sept, 1H, CH, $^3J_{\text{HH}} = 7.0$ Hz). ¹³C NMR (75 MHz) δ : *rotamer anti*: 18.5 (N-CH(CH₃)₂), 18.7 (S-CH₂-CH₂-CN), 31.2 (S-CH₂-CH₂-CN), 53.2 (CH), 118.1 (CN), 126.2 (=C), 135.5 (=C), 186.9 (C=Se); *rotamer syn*: 20.7 (N-CH(CH₃)₂), 19.0 (S-CH₂-CH₂-CN), 33.3 (S-CH₂-CH₂-CN), 56.8 (CH), 118.2 (CN), 128.9 (=C), 136.8 (=C), 187.7 (C=Se). HRMS (ASAP, QTOF 2) calcd for C₁₂H₁₆N₃S₃Se⁺: 377.96716, found: 377.9668.

N-*i*Pr-1,3-thiazoline-2-one **4**

To a solution of 1,3-thiazoline-2-thione **1** (2 g, 12.6 mmol) in dry acetone (15 mL) was slowly added iodomethane (1.0 mL, 15.1 mmol). The reaction was stirred at room temperature for 2 h under inert atmosphere. The medium was cooled to 0 °C and the precipitate was filtered and washed with a minimum amount of cold acetone. The 2-thiomethyl-1,3-thiazolium salt was dried under vacuum. The thiazolium salt was obtained in quantitative yield (3.8 g); mp = 176 °C. ¹H NMR (300 MHz) δ : 1.72 (d, 6H, CH₃, $^3J_{\text{HH}} = 7.4$ Hz), 3.06 (s, 3H, SCH₃), 4.77 (sept, 1H, CH, $^3J_{\text{HH}} = 7.5$ Hz), 8.40 (d, 1H, CH, $^3J_{\text{HH}} = 6.9$ Hz), 8.42 (d, 1H, CH, $^3J_{\text{HH}} = 6.9$ Hz). ¹³C NMR (75 MHz) δ : 19.4 (SCH₃), 21.8 (CH₃), 56.9 (CH), 124.7 (C=C), 133.7 (C=C), 172.8 (C⁺-SMe). HRMS (ESI, QTOF 2) calcd for C₇H₁₂NS₂⁺: 174.04112, found: 174.0410. Anal. calcd for C₇H₁₂NS₂I: C, 27.90; H, 3.99; N, 4.65; S, 21.30. Found: C, 27.81; H, 4.20; N, 4.85; S, 21.48. Sodium methanolate solution (1 M in MeOH, 9.4 mL, 9.4 mmol) was added under inert atmosphere to a solution of the thiazolium salt (2.2 g, 7.3 mmol) in dry methanol (20 mL). The reaction was stirred at room temperature for 5 h, extracted with dichloromethane and washed with saturated NaCl solution. The concentrated solution was purified by column chromatography on silica gel using CH₂Cl₂/Et₂O (9.9/0.1) as eluent and thiazoline-2-one **4** was isolated as yellow oil in 87% yield (0.91 g). R_f = 0.35 (SiO₂, CH₂Cl₂/Et₂O, 9.9/0.1). ¹H

NMR (300 MHz) δ : 1.25 (d, 6H, CH₃, $^3J_{\text{HH}} = 7.4$ Hz), 4.48 (sept, 1H, CH, $^3J_{\text{HH}} = 7.4$ Hz), 6.06 (d, 1H, CH, $^3J_{\text{HH}} = 6.9$ Hz), 6.58 (d, 1H, CH, $^3J_{\text{HH}} = 6.9$ Hz). ^{13}C NMR (75 MHz) δ (ppm): 21.5 (CH₃), 45.9 (CH), 100.8 (C=C), 120.6 (C=C), 171.1 (C=O). HRMS (ASAP, QTOF 2) calcd for C₆H₁₀NSO⁺: 144.04831, found: 144.0485.

Bis(4,5-cyanoethylthio)-1,3-thiazoline-2-one 5.

Under inert atmosphere at 0°C, LDA was prepared by adding *n*BuLi (3.9 mL, 6.30 mmol, 1.6 M in hexane) to a solution of diisopropylamine (0.9 mL, 6.30 mmol) in 10 mL of anhydrous THF. The LDA solution was added to a solution of 1,3-thiazoline-2-one **4** (0.60 g, 4.20 mmol) in 40 mL of anhydrous THF at -10°C. After stirring for 30 minutes, sulfur (0.20 g, 6.30 mmol) was added to the reaction mixture, and the medium was stirred for an additional 30 minutes before the addition of LDA (8.40 mmol prepared from 5.3 mL of *n*BuLi, 1.6 M in hexane, and 1.2 mL of diisopropylamine in 15 mL of anhydrous THF). The reaction mixture was stirred for 3 hours, and sulfur was added (0.27 g, 8.40 mmol), followed 30 min later by the addition of 3-bromopropionitrile (3.5 mL, 41.9 mmol). The temperature was allowed to rise to room temperature and then the reaction was stirred overnight. Tetrahydrofuran was evaporated and the residue was extracted with dichloromethane. The organic phase was washed with water and dried over MgSO₄. The resulting oil was purified by column chromatography on silica gel using CH₂Cl₂/Et₂O (9.8/0.2) as eluent. Compound **5** was isolated as brown orange oil in 36% yield (0.26 g). $R_f = 0.27$ (SiO₂, CH₂Cl₂/Et₂O, 9.8/0.2). ^1H NMR (300 MHz) δ : 1.54 (d, 6H, CH₃, $^3J_{\text{HH}} = 6.9$ Hz), 2.72 (t, 4H, CH₂, $^3J_{\text{HH}} = 6.9$ Hz), 3.04 (t, 4H, CH₂, $^3J_{\text{HH}} = 6.9$ Hz), 4.77 (sept, 1H, CH, $^3J_{\text{HH}} = 6.9$ Hz). ^{13}C NMR (75 MHz) δ : 18.2 (S-CH₂-CH₂-CN), 18.4 (S-CH₂-CH₂-CN), 19.4 (CH₃), 31.4 (S-CH₂-CH₂-CN), 31.9 (CH), 116.7 (CN), 117.2 (C=C), 131.1 (C=C), 169.1 (C=O). HRMS (ESI, QTOF 2) calcd for C₁₂H₁₅N₃ONaS₃⁺: 336.0275, found: 336.0272.

[PPh₄][Au(*i*Pr-thiazYdt)₂] (Y = O, Se). To a dry two-neck flask containing 1,3-thiazoline-2-selone **3** (0.30 g, 0.80 mmol) or 1,3-thiazoline-2-one **5** (0.15 g, 0.87 mmol) a solution of sodium methalonnate 1M in MeOH was added (8.7 mL for **5** and 6 mL for **3**) under argon atmosphere at room temperature. After stirring for 30 min, a solution of potassium tetrachloroaurate (III) hydrate (KAuCl₄·H₂O) (**3**: 0.18 g, 0.48 mmol; **5**: 0.20 g, 0.52 mmol) in 7 mL of anhydrous methanol was added to the reaction mixture followed, 5 h later, by the addition of tetraphenylphosphonium chloride (PPh₄Cl) (**3**: 0.18 g, 0.48 mmol, **5**: 0.20 g, 0.52 mmol) in 7 mL of anhydrous methanol. Then the reaction was stirred overnight at room temperature under argon atmosphere. The dark brown solution was filtered and concentrated in vacuo. The resulting solid was washed with MeOH and recrystallized from acetonitrile.

[PPh₄][Au(*i*Pr-thiazSedt)₂], C₃₆H₃₄AuN₂PS₈; black green crystals. Yield: 0.22 g (52%); mp = 180 °C. ¹H NMR (300 MHz) at room temperature δ 1.58 (broad signal, 12H, CH₃, ³J_{HH} = 7.1 Hz), 5.78 (broad signal, 2H, CH, ³J_{HH} = 7.0 Hz), 7.63 (m, 8H, CH_{Ar}), 7.78 (m, 8H, CH_{Ar}), 7.93 (m, 4H, CH_{Ar}). Anal. calcd for C₃₆H₃₄AuN₂PS₈: C, 40.30; H, 3.19; N, 2.61. Found: C, 40.24; H, 3.46; N, 2.98.

[PPh₄][Au(*i*Pr-thiazOdt)₂], C₃₆H₃₄AuN₂PO₂S₆; black green crystals. Yield: 0.14 g (34%); mp = 184 °C. ¹H NMR (300 MHz) at room temperature δ 1.45 (d, 6H, CH₃, ³J_{HH} = 7.1 Hz), 1.49 (d, 6H, CH₃, ³J_{HH} = 7.1 Hz), 4.45 (sept, 2H, CH, ³J_{HH} = 7.0 Hz), 4.46 (sept, 2H, CH, ³J_{HH} = 7.0 Hz), 7.59 (m, 8H, CH_{Ar}), 7.73 (m, 8H, CH_{Ar}), 7.87 (m, 4H, CH_{Ar}). ¹³C NMR (75 MHz) δ: 20.2 (N-C(CH₃)₃), 49.7 (N-C(CH₃)₃), 100.7 (C=C), 117.0 (C_{Ar}), 118.2 (C_{Ar}), 123.5 (C=C), 130.8 (C_{Ar}), 134.5 (C_{Ar}), 135.9 (C_{Ar}), 177.4 (C=O). UV-vis-NIR (CH₂Cl₂) λ (nm), ε (M⁻¹·cm⁻¹): 310, 33480; 260, 49520; 232, 70948. HRMS (ESI, Q-Exactive) calcd for C₁₂H₁₄N₂O₂S₆Au⁻: 606.90507, found: 606.9051. Anal. calcd for C₃₆H₃₄AuN₂PO₂S₆: C, 45.66 ; H, 3.62 ; N, 2.99. Found: C, 45.74 ; H, 3.51 ; N, 2.66.

4.3. X-ray crystallography

Single crystal diffraction data were collected on a D8 VENTURE Bruker AXS diffractometer for complex $[\text{PPh}_4][\text{Au}(i\text{Pr-thiazOdt})_2]$ and on an APEXII Bruker AXS diffractometer for complex $[\text{PPh}_4][\text{Au}(i\text{Pr-thiazSedt})_2]$, (Mo- $K\alpha$ radiation, $\lambda = 0.71073 \text{ \AA}$). The structures were solved by direct methods using the *SIR97* program [20], and then refined with full-matrix least-square methods based on F^2 (*SHELXL-97*) [21]. All non-hydrogen atoms were refined with anisotropic atomic displacement parameters. H atoms were finally included in their calculated positions. The squeeze procedure implemented in PLATON [22] was used for $[\text{PPh}_4][\text{Au}(i\text{Pr-thiazSedt})_2]$ structure refinement. Crystallographic data on X-ray data collection and structure refinements are given in Table 6 for both complexes.

4.4. Computational Details.

Full geometry optimization with Density Functional Theory [23] calculations were performed with the hybrid Becke-3 parameter exchange functional [24] and the Lee-Yang-Parr non local

correlation functional [25] (B3LYP) implemented in the *Gaussian 03* (revision D.02) program suite [26] using the 6-31G* basis set [27] and the LANL2DZ basis set [28].

Highlights

Influence of the exocyclic chalcogen atoms of the ligands on the properties of gold dithiolene complexes.

Influence of the size, electronegativity and polarizability of the exocyclic chalcogen atom.

Conformational equilibrium between rotamers.

Exocyclic oxygen atoms increases the potential domain of stability of the neutral species.
