HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers. L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
Application of the Curtius rearrangement to the synthesis of 1'-aminoferrocene-1-carboxylic acid derivatives

William Erb,†‡ Gael Levanen,§ Thierry Roisnel,∥ and Vincent Dorcet¶

The shortest synthesis of N-protected 1'-aminoferrocene-1-carboxylic acid from readily available ferrocene-1,1'-dicarboxylic acid is reported. 1'-Azidocarboxyferrocene-1-carboxylic acid was first obtained by reaction of the latter with diphenylphosphoryl azide. It was then converted into four amino acids by a Curtius rearrangement conducted in the presence of tert-butanol, benzyl alcohol, 9-fluorenemethanol or allyl alcohol. The benzyl and allyl carbamate derivatives are reported and characterized for the first time. The four corresponding new succinimidyl activated esters were also prepared and their usefulness was demonstrated in peptide coupling. Various structures were elucidated by X-ray crystallography, including 1'-azidocarboxyferrocene-1-carboxylic acid and 1,1'-diazidocarbonyl ferrocene.

Introduction

Since the pioneering study of Herrick and co-workers on the use of ferrocene-1,1'-dicarboxylic acid as a turn mimic in peptides,1 a lot of work has been done to understand, rationalize and use this organometallic scaffold in medicinal chemistry.2–4 Three types of peptides have been reported based on ferrocene-1,1'-dicarboxylic acid (type I), ferrocene-1,1'-diamine (type II), and 1'-aminoferrocene-1-carboxylic acid (Fca, type III). Type I and II allow the formation of parallel peptide strands whereas type III leads to antiparallel orientation, typical of natural peptides. Since then, the groups of Kraatz, Metzler-Nolte, Rapić and Heinze have been especially prolific in the study of this unnatural amino acid. Indeed, Fca has been incorporated in peptides of various lengths for conformation studies5–14 or for detection and sensing.15–18 It has also been used to access polyferrocenic structures to study electronic communication between the redox-active units19–26 and in various scaffolds for specific applications.27–30

Surprisingly, despite the wide use of Fca, the price of its commercially available N-protected derivatives remains expensive, probably due to the lack of easy and fast syntheses. The first approach was reported by Butler and co-workers in 1998 starting from 1,1'- dibromoferrocene (Scheme 1, A).37 A first halogen/metal exchange using butyllithium, followed by trapping with O-benzylhydroxylamine affords 1'-bromoferroacen-1-amine. A second halogen/metal exchange followed by trapping with carbon dioxide leads to Fca. Being a zwiterion, its purification proves highly difficult and esterification is necessary to get the pure product in an overall 44% yield. However, functional groups transformations remain to be done to obtain a product suitable for peptide coupling.

The same year, Okamura et al. proposed their own synthesis of Boc-protected Fca starting from ferrocenecarboxylic acid (Scheme 1, B).38 N-Acetamidoferrocene is first made by a sequence of ester activation-azidation-Curtius rearrangement in the presence of acetic anhydride. A regioselective Friedel-Crafts reaction followed by tBuOK-mediated ketone cleavage leads to the free carboxylic acid. Acetamide deprotection and tert-butyl carbamate (Boc) protection finally afford protected Fca in an overal 10% yield. In 2002, Rapić and co-workers proposed an original approach based on a bis-ester desymmetrization (Scheme 1, C).39 Starting from 1,1'-diacetylferrocene, bromine oxidation followed by esterification leads to the corresponding bis-ester. Selective hydrolysis then conducts to the monocarboxylic acid which is readily converted to the Boc-protected amino group by a sequence of acid activation-azidation-Curtius rearrangement. Ester saponification finally affords Boc-protected Fca. The use of benzyl alcohol in place of tert-butyl alcohol similarly provides benzyl carbamate (Cbz)-protected Fca. Therefore, from 1,1'-diacetylferrrocene, six steps are required to access Boc- and Cbz-protected Fca in 19% and 28.5% yield, respectively. Finally, in 2004, Heinze and co-workers reported an improvement of Okamura’s synthesis (Scheme 1, D).40 The main differences lie in the synthesis of N-acetamidoferrocene, here obtained from iodoferrocene by a N-arylation-phthalimide deprotection-amidation sequence. Fluorenylethyl carbamate (Fmoc)-protected Fca is finally obtained following Okamura’s sequence in a 32% overall yield. Although an improvement is here clearly noticed, all of these syntheses remain time consuming, due to successive introduction of each substituent or tedious protection-deprotection steps.
In our eyes, the desymmetrization proposed by Butler and co-workers clearly appears as the shortest way to Fca. However, amination followed by carboxylation clearly complicates the isolation of pure material and we thought to reverse these steps, thus starting from ferrocene-1,1′-dicarboxylic acid. Although dicarboxylic acids are classical substrates to access carbamate-protected amino acids, their desymmetrization are usually performed by bis-ester saponification,\(^1\)mono-ester formation\(^4\)or cyclic anhydride opening (either with an azide or NH\(_3\)) reactions.\(^4\) All these approaches require multiple steps, and shorter routes have been less studied. They are based on Schmidt reaction or Curtius rearrangement, and explosive hydrazoic acid limited the application of the Curtius reaction or Curtius rearrangement is a reaction of the intermediate isocyanate with nucleophiles,\(^4\)the isocyanate can also be converted carboxylic acid into an isocyanate through an acyl azide intermediate. High reactive, the isocyanate can then be trapped by nucleophiles to access amines, amides,\(^5\)ureas,\(^6\) carbamates,\(^7\)thiocarbamates,\(^8\) and sulfonylureas.\(^9\) They can also be used in cycloaddition or electrocyclization.\(^10\) Introduced in 1972 by Yamada, the use of diphenylphosphoryl azide (DPPA) allows ester activation, azidation and Curtius rearrangement to be easily done in one-pot, facilitating the access towards isocyanates.\(^11\)\(^12\) However, its use for the desymmetrization of bis-carboxylic acid carbocycles has been scarcely reported. In 1996, Kahl and co-workers reported the transformation of carboranedicarboxylic acids into their corresponding amino acids under reaction with DPPA; different yields were obtained for each isomer: 83% (p), 80% (m) and 54% (o).\(^13\) Later, Berkesel reported low yields in the DPPA-mediated transformation of cyclohexane-1,2-dicarboxylic acid.\(^14\) In 2001 and 2003, pyridine-2,6- and -3,5-dicarboxylic acids were engaged in such desymmetrizations by Cho\(^15\)and Nakayama\(^16\) with moderate yields, 45% and 46% respectively. Therefore, we can divide the substrates used in this approach into two classes depending on if (1) both carboxylic acids are close from each other or (2) carboxylic acids are spaced by a rigid linker. With a distance of 3.3 Å between the two functional groups,\(^17\)ferrocene-1,1′-dicarboxylic acid belongs to the first category (similar distances were noticed at the solid state for cyclohexane-1,2-dicarboxylic acid, 3.0 Å, and for ω-carboranes, between 3.1 to 3.2 Å).\(^18\)\(^19\) Here, we report our efforts to control such challenging transformation toward the shortest synthesis of N-protected Fca.

### Results and discussion

We initially studied the Curtius rearrangement to access Boc-protected Fca (1) in a one-pot manner by the desymmetrization of ferrocene-1,1′-dicarboxylic acid (2). In a model reaction, 2 was suspended in toluene and treated with an excess of triethylamine and one equivalent of DPPA (Table 1). To favor the reaction of the intermediate isocyanate with tert-butanol rather than with the remaining carboxylate, we used a 20-fold excess of alcohol. High dilution conditions (0.04 mol.L\(^{-1}\)) were also applied to limit intermolecular side-reactions. After 2h, we pleasingly observed the formation of the title product in an encouraging 20% yield. The use of tBuOH as solvent resulted in a major drop in the yield and we therefore kept toluene (entry 2). However, regardless of the reaction time (entries 1, 3 and 4), the order of addition of reagents (entry 5) or the excess of DPPA (entry 6), the yield invariably remained below 20%.

Figure 1. Molecular structure of compound 5 (thermal ellipsoids shown at the 30% probability level).

During this study, we also elucidated the solid-state structure of 3 and 4 by X-ray crystallography (Figures 2 and 3). In both cases, the cyclopentadienyl rings (Cp) are in an eclipsed conformation (3: C15-C1-C6-C5-C2 pseudo torsion angle 1.0°, Cg denotes the centroids of the respective Cp ring; 4: C15-C15-Cg2-C2 pseudo torsion angle 0.6°), and coplanar, as indicated by the Cp-Cp planes angles (3: 1.4°; 4: 1.1°). In 3, the Cp substituents are slightly less tilted when compared to 4 (3: C1-C5-C6-O7 5.5°, C14-C15-C16-O27 3.4°; 4: C1-C5-C6-O8 7.2°, C15-C15-C16-O27 11.5°).

Figure 2. Molecular structure of compound 3 (thermal ellipsoids shown at the 30% probability level).

Figure 3. Molecular structure of compound 4 (thermal ellipsoids shown at the 30% probability level).

We then studied the thermal Curtius rearrangement of 4 in toluene at 110 °C. In the absence of tBuOH, we noticed the fast disappearance of the N3 stretching band. However, the isocyanate band (2270 cm⁻¹) remained small during the reaction, to virtually

a 2, NEt3 and DPPA were mixed for 1h at rt before addition of tBuOH and reflux. b 1.2 equiv of DPPA was used.

to identify the problematical step, we separately studied each stage of the process. We initially focused our attention onto the formation of the intermediate acyl azide. In a first reaction, ferrocene-1,1'-dicarboxylic acid (2) was mixed with a slight excess of triethylamine and one equivalent of DPPA in CH2Cl2 at room temperature. The reaction took 24h to reach completion and afforded, after column chromatography, 31.5% of 1,1'-diazidocarboxylic acid (3) and 29.5% of 1'-azidocarboxylic acid (4) (Table 2, entry 1).

As the solubility of 2 in CH2Cl2 is rather limited, we next used an excess of base to favor the formation of a bis-ammonium salt. Not only the solubility increased, but the reaction time shortened to 4h (reaction monitored by IR, N1 stretching band, DPPA: 2170 cm⁻¹; 3 and 4: 2138 cm⁻¹, see SI) and the ratio of mono-azide changed (entry 2). Keeping a 4-fold excess of base, the reaction mixture was concentrated up to 0.52 mol.L⁻¹ and the ratio of bis-azide changed (entry 2). Keeping a 4-fold excess of base, the reaction mixture was concentrated up to 0.52 mol.L⁻¹, resulting in shorter reaction times and in higher yields of 4 (entries 2-5). Finally, increasing the temperature from rt to 40 °C resulted in a very fast reaction (entry 6). Pleasingly, gram-scale reaction could be conducted in a still correct yield of 4 (entry 7).

a Reaction performed on 1.3 mmol of 2. b Reaction performed at 40 °C. c Reaction performed on 8 mmol of 2.

Even if an excess of base seems to promote the formation of the monoazide 4, we were concerned by the double deprotonation of ferrocene-1,1'-dicarboxylic acid (2) which could lead to 3. Therefore, we mixed 2 with a 4-fold excess of base and, after evaporation of the solvent, a 1H NMR study showed that double deprotonation occurred only to a moderate extent (1.0:3 mono/bis-ammonium ratio estimated). Furthermore, we managed to obtain crystals suitable for X-ray crystallography by slow evaporation of the solvent from the crude reaction mixture. The solid-state structure was consistent with the NMR results evidencing the main presence of the mono-ammonium 5 (Figure 1).
disappear after 1h heating (see SI). The formation of a black precipitate as the reaction proceeds was also noticed, thus questioning the stability of the intermediate isocyanate. Indeed, addition of tBuOH after 1h of heating only resulted in traces of amino acid.

Therefore, as the isocyanate derivative appears unstable on heating, we next conducted the Curtius rearrangement in the presence of tBuOH. Using a 20-fold excess of alcohol in diluted conditions (0.02 mol.L\(^{-1}\)), we managed to isolate 37.5 % of 1 (Table 3, entry 1), the rest of the mass balance being represented by baseline spots. We next raised the concentration up to 0.16 mol.L\(^{-1}\) and pleasingly observed better yields (up to 58 %, entries 1-4). However, if tBuOH is pretty cheap, the price of other alcohols, such as 9-fluorenemethanol, is more concerning when such an excess has to be used. The impact of the amount of tBuOH was next studied and we found that the reaction works equally with only 2.5 equivalents (entries 4-7). However, even if the use of Brønsted and Lewis acids to accelerate the reaction has already been reported, Boc group deprotection was also observed, resulting in the formation of unprotected Fca (entries 8 and 9). The use of lower temperature did not allow us to isolate any protected amino acid in these conditions. However, gram-scale reaction is also possible with an almost similar outcome (entry 10).

\(^{a}\) Reaction performed on 0.4 mmol of 4. \(^{b}\) Reaction performed in AcOH. \(^{c}\) Unprotected Fca observed in crude reaction mixture by NMR. \(^{d}\) Reaction performed in dioxane with 1 equiv of BF\(_2\)OEt\(_2\). \(^{e}\) Reaction performed on 5 mmol of 4.

Having identified the best conditions for each step, we combined them toward a one-flask, two-step protocol toward N-Boc protected Fca. We mixed ferrocene-1,1'-dicarboxylic acid (2) with an excess of NET\(_3\) and one equivalent of DPPA in CH\(_2\)Cl\(_2\) at 40 °C. After 10 min, volatiles were removed under vacuum. Toluene and tBuOH were added and the reaction mixture was heated at 110 °C for one hour. However, a disappointing 23% yield was noticed (Table 4, entry 1). As the concentration step might favor unwanted intermolecular side reactions, we moved to dioxane to avoid a solvent switch, but this resulted in a yield drop (entry 2). Concerned with the excess of base, we next filtered the crude reaction mixture after acyl azide formation over acid resin, but no improvement was noticed (entry 3).

\(^{a}\) Reaction mixture filtrated over Amberjet 1000H resin before rearrangement.

Puzzled by these last results, we reasoned that the main difference in the two-step procedure was the intermediate purification of 3 and that, in the one-flask procedure, both 3 and 4 were present. Therefore, we subjected a mixture of pure 3 and 4 in a 1:1.9 ratio, as obtained in the first step, to the Curtius rearrangement (Scheme 2). The yield of 1 dropped from 70% (when pure 3 is used) to 20% in this last case, therefore indicating that the presence of mono- and bis-acyl azide was detrimental to the outcome of the reaction.

### Scheme 2. Curtius rearrangement of a mixture of 3 and 4.

It is difficult to rationalize why the presence of multiple isocyanides favors decomposition. However, it has been proposed that, on prolonged heating, thermolysis of ferrocenyl isocyanate could lead to iron-stabilized nitrene, able to deliver the corresponding amine by proton abstraction from the solvent.\(^{52}\) The latter could then react with a remaining isocyanate to give various ureas.\(^{19,39}\) Carboxylic acids are also known to react with isocyanates and generate mixed carbamic-carboxylic anhydrides.\(^{93-96}\) Such reactive groups could further generate symmetrical and unsymmetrical ureas. As we used disubstituted substrates, all these reactions could lead to polyureas and decomposition products. Indeed, after the Curtius rearrangement step, an insoluble black precipitate was invariably observed, as well as baseline spots by thin-layer chromatography.

As it proved difficult to perform a one-flask reaction, we went back to a two-step protocol and made four N-protected Fca by the reaction of 4 with various alcohols. The best yield was observed with tBuOH (1), whereas benzyl alcohol, 9-fluorenemethanol and allyl alcohol reacted equally to give the corresponding Fca derivatives (7-9, Scheme 3).

### Scheme 3. Curtius rearrangement of 4 applied to the synthesis of protected Fca.

No analytical details are reported on the Cbz derivative 7 whereas the Alloc-protected Fca 9 is new. Consequently, we carried out the complete elucidation of their structure in both solution and solid-
state. In solution, 2D NMR experiments were performed, and selected NOESY and HMBC correlations are depicted in Figure 4. For all the Fca derivatives, strong NOESY correlations were noticed between the NH and the adjacent ferrocenic protons. Additional correlations were also observed between the NH and the proton of the upper Cp ring, suggesting a certain degree of free rotation of the two Cp rings in DMSO-d6.

Figure 4. Selected NOESY (red arrows) and HMBC (black arrows) correlations observed by 2D NMR for 1, 7-9. Plain and dash arrows indicate strong and weak correlations, respectively.

At the solid state, the Alloc derivative 9 adopts a dimer structure, as reported for the Boc and Fmoc analogs (Figure 5). Indeed, two molecules of 9 are connected by two eight-membered rings: one between the two carboxylic acids with O8-H8···O27 and O28-H28···O8 hydrogen bonds (1.8 (5) and 1.9 (6) Å, respectively; the other made of hydrogen bonds between the NH carbamate and one oxygen of the other carbamoyl moiety (2.0 Å for both N14-H14···O36 and N34-H34···O18). According to their lengths and corresponding angles, they are strong hydrogen bonds. For both molecules of the dimer, Cp rings of each ferrocenyl group are almost coplanar (Cp-Cp planes angle, molecule A: 2.0°; molecule B: 1.0°) but slightly eclipsed (pseudo rotation angle, molecule A: C25-Cg3···Cg4-C33: 12.7°; molecule B: C5-Cg1···Cg2-C13: 14.2°).

Figure 5. Molecular structure of compound 9 (thermal ellipsoids shown at the 30% probability level).

On the other hand, a molecule of water co-crystallized with the Cbz derivative 7, resulting in a completely different hydrogen bonding network (Figures 6 and 7). Due to that additional water molecule, dimers are no longer observed. Hydrogen bonds are present between the carboxyl acid and water (O8-H8···OW1, 1.74 (2) Å) and between water and the CO carbamate (OW1-HW1A···O1 and OW3-HW1B···O8, 1.89 (2) and 1.86 (3) Å, respectively), as depicted on Figure 7. A last N16-H16···O7 hydrogen bond (2.16 (2) Å) helps to structure the crystal. The Cp rings appear almost coplanar (Cp-Cp planes angle 2.7°) and adopt an eclipsed conformation (pseudo torsion angle C5-Cg1···Cg2-C13: 1.0°).

Figure 6. Molecular structure of compound 7 (thermal ellipsoids shown at the 30% probability level).

Figure 7. Hydrogen bonds observed at the solid state for 7 (H atoms not involved in hydrogen bonds were omitted for clarity).

The reaction of N-acetylated and N-Boc Fca with 1-hydroxybenzotriazole (HOBt) have been reported to deliver the activated esters in good yields. In order to extend the chemistry of Fca derivatives, we here prepared the four activated esters 10-13 by reacting the carboxylic acid with N-hydroxysuccinimide (NHS) in the presence of 1-ethyl-3-(3-dimethylaminopropyl)carbodiimide (EDC) as coupling agent (Scheme 4). Good yields were obtained, apart for 10 for which the formation of the corresponding anhydride 14 was also noticed.

In solution, NOESY NMR experiments helped elucidate the structure of the four activated esters (Figure 8). First, the absence of any correlation between succinimidy’s methylene protons and the carbamate protecting group tends to suggest that the two substituents are away from each other. Then, the moderate to strong correlations observed between the carbamate NH and ferrocenic protons on the upper Cp ring suggest that both substituents are opposite. The correlation between Boc group’s methyl protons and the ferrocenic protons on the upper Cp ring support that hypothesis.
This was confirmed by the X-ray crystal structure of 10 (Figure 9).

Conclusions

We studied the desymmetrizing Curtius rearrangement from ferrocene-1,1′-dicarboxylic acid toward N-protected 1′-aminoferrocene-1-carboxylic acid. A careful optimization of each step revealed the thermal instability of 1′-isocyanatoferrocene-1-carboxylic acid and the probable formation of polyferrocenic amides when two different acyl azides are mixed.

We therefore developed a two-stage protocol, able to deliver various N-protected Fca in good yields. They were further elaborated into succinimidyl activated esters, for coupling with amines. The structure of various products was elucidated both at the solid state and in solution. It makes little doubt that this shortest synthesis of 1′-aminoferrocene-1-carboxylic acid derivatives will help chemists to access original structures for various applications. Our efforts towards such biologically active ferrocene derivatives and sensors will be reported in due course.

Experimental

General Details. Unless otherwise stated, all the reactions were performed under air. Column chromatography separations were achieved on silica gel (40-63 μm). Melting points were measured on a Kofler apparatus. IR spectra were taken on a Perkin-Elmer Spectrum 100 spectrometer. 1H and 13C Nuclear Magnetic Resonance (NMR) spectra were recorded either (i) on a Bruker Avance III HD spectrometer at 300 MHz and 75 MHz, respectively, or (ii) on a Bruker Avance III HD at 500 MHz and 125.7 MHz, respectively. 1H chemical shifts (δ) are given in ppm relative to the solvent residual peak and 13C chemical shifts are relative to the central peak of the solvent signal.

For 3, 4, 5, 7, 9 and 10, the X-ray diffraction data were collected using D8 VENTURE Bruker AXS or APEXII Bruker AXS diffractometers at the temperature given in the crystal data. The samples were studied with monochromatized Mo-Kα radiation (λ = 0.71073 Å). The structure was solved by dual-space algorithm using the SHELXT program and then refined with full-matrix least-squares methods based on F2 (SHELXL). All non-hydrogen atoms were refined with anisotropic atomic displacement parameters. H atoms were finally included in their calculated positions. The molecular diagrams were generated by MERCURY (version 3.5.1). Ferrocene-1,1′-dicarboxylic acid is commercially available but can also be prepared from ferrocene following the procedure described in SI.

Tyriethylammonium 1′-carboxyferrocene-1-carboxylate (5) and bis triethlylammonium 1,1′-ferrocene carboxylate mixture.

Triethylamine (167 mg, 1.2 mmol, 4.0 equiv) was added to a solution of ferrocene-1,1′-dicarboxylic acid (2, 82.2 mg, 0.3 mmol, 1.0 equiv) in DCM (5.0 mL). After 5 min stirring at room temperature, volatiles were removed under vacuum to give the crude product as an orange solid (quant.). It is composed of a 1:0.3 mixture of mono- and bis-ammonium. mp 240-242 °C (decomp.; IR (ATR): 2474 (br), 1682, 1588, 1461, 1380, 1320, 1244, 1154, 1022, 820, 787, 725 cm⁻¹; 1H NMR (300 MHz, CDCl3) (major ammonium described) δ 4.66 (t, J = 1.8 Hz, 4H, 4 x FeCH), 4.34 (t, J = 1.8 Hz, 4H, 4 x FeCH) 3.01 (q, J = 7.2 Hz, 8H, 4 x CH2), 2.25 (t, J = 7.2 Hz, 12H, 4 x CH2); 13C NMR (75.4 MHz, CDCl3) (major ammonium described) δ 175.6 (2 x C=O), 77.2 (2 x FeC, seen by HMBCC correlations), 72.2 (4 x FeCH), 71.8 (4 x FeCH), 45.1 (4 x CH2), 9.2 (4 x CH3).

Crystal data for 5. C24H24FeO4, C6H12N; M = 375.24, T = 150(2) K, orthorhombic P b c a, a = 14.193(7), b = 11.681(4), c = 21.035(10) Å, V = 3487(3) Å³. Z = 8, d = 1.429 g cm⁻³, μ = 0.886 mm⁻¹. A final refinement on F² with 3990 unique intensities and 221 parameters converged at wR(F²) = 0.1203 (R(F) = 0.0493) for 3372 observed reflections with l > 2σ(l).

1′-Azidocarboxyferrocene-1-carboxylic acid (4).

DPPA (280 μL, 358 mg, 1.3 mmol, 1.0 equiv) was added to a solution of ferrocene-1,1′-dicarboxylic acid (2, 356 mg, 1.3 mmol, 1.0 equiv) and trimethylamine (725 μL, 526 mg, 5.2 mmol, 4.0 equiv) in DCM (2.5 mL). After 10 min stirring at room temperature, HCl (1M, 30 mL) was added and the reaction mixture was extracted with DCM (3 x 20 mL). The combined organic layers were dried over MgSO₄, filtered and concentrated under vacuum to give the crude product. This was purified by column chromatography on silica, eluting with EtOAc/heptane (50:50 to 40:60) with few drops of TFA to give 1′-diazidocarboxyferrocene (92.1 mg, 22%) and 1′-dicarboxyferrocene.
azidocarbonylferrocene-1-carboxylic acid 4 (239 mg, 0.8 mmol) and benzyl alcohol (207 µl, 216 mg, 2.0 mmol) afforded the title product as an orange solid (129 mg, 53%). mp 116-118 °C; IR (ATR): 2987 (br), 1633, 1584, 1508, 1476, 1380, 1360, 1333, 1304, 1275, 1250, 1170, 1091, 1026, 930, 738 cm⁻¹; ¹H NMR (500 MHz, DMSO-d⁶) δ 11.97 (s, 1H, CO₂H), 8.54 (br s, 1H, NH), 4.60 (s, 2H, CH₂), 4.49 (br s, 2H, CH₂), 4.32 (s, 2H, CH₂), 3.92 (s, 2H, CH₃), 1.45 (s, 9H, CH₃); ¹³C NMR (125.7 MHz, DMSO-d⁶) δ 171.9 (C=O,CO₂H), 152.9 (C=O,carbamate), 98.4 (FcC), 79.2 (FcC), 78.5 (CH₃C₆H₄), 72.7 (2 x FcCH), 70.4 (2 x FcCH), 65.3 (2 x FcCH), 60.6 (2 x FcCH), 28.1 (CH₃C₆H₄). Anal. Calc. for C₃₁H₂₇FeNO₁₁: C, 55.67; H, 5.55; N, 4.06. Found: C, 55.78; H, 5.67; N, 4.15.

1’-(Benzoylcarbonyl)aminoferrocene-1-carboxylic acid (7). The general procedure 1 using 1’-azidocarbonylferrocene-1-carboxylic acid (4, 119 mg, 0.4 mmol) and benzoyl chloride (94.0 µl, 71.4 mg, 1.0 mmol) afforded the title product as a yellow oil (56.5 mg, 53%). mp 145-150 °C (lit.⁸ 145-146 °C); IR (ATR): 2974 (br), 1698, 1668, 1488, 1394, 1362, 1287, 1160, 1069, 1020, 945, 807, 777 cm⁻¹; ¹H NMR (500 MHz, DMSO-d⁶) δ 11.97 (s, 1H, CO₂H), 8.54 (br s, 1H, NH), 4.60 (s, 2H, CH₂), 4.49 (br s, 2H, CH₂), 4.32 (s, 2H, CH₂), 3.92 (s, 2H, CH₃), 1.45 (s, 9H, CH₃); ¹³C NMR (125.7 MHz, DMSO-d⁶) δ 171.9 (C=O,CO₂H), 152.9 (C=O,carbamate), 98.4 (FcC), 79.2 (FcC), 78.5 (CH₃C₆H₄), 72.7 (2 x FcCH), 70.4 (2 x FcCH), 65.3 (2 x FcCH), 60.6 (2 x FcCH), 28.1 (CH₃C₆H₄). Anal. Calc. for C₃₁H₂₇FeNO₁₁: C, 55.67; H, 5.55; N, 4.06. Found: C, 55.78; H, 5.67; N, 4.15.

1’-(Benzoylcarbonyl)aminoferrocene-1-carboxylic acid (7). The general procedure 1 using 1’-azidocarbonylferrocene-1-carboxylic acid (4, 239 mg, 0.8 mmol) and benzyl alcohol (207 µl, 216 mg, 2.0 mmol) afforded the title product as an orange solid (154 mg, 51%). mp 128-130 °C (lit.⁹ 133-134 °C); IR (ATR): 3305, 2921 (br), 1702, 1645, 1566, 1478, 1396, 1287, 1257, 1209, 1170, 1091, 1026, 930, 738 cm⁻¹; ¹H NMR (500 MHz, DMSO-d⁶) δ 12.02 (br s, 1H, NH), 9.01 (s, 1H, NH), 7.40-7.36 (m, 4H, 4 x ArCH), 7.34-7.33 (m, 1H, ArCH), 5.11 (s, 2H, CH₂), 4.62 (s, 2H, 2 x FcCH), 4.52 (s, 2H, 2 x FcCH), 4.32 (s, 2H, 2 x FcCH), 3.95 (s, 2H, 2 x FcCH); ¹³C NMR (125.7 MHz, DMSO-d⁶) δ 171.8 (C=O,C), 153.5 (C=O,carbamate), 133.4 (ArCH), 128.4 (2 x ArCH), 127.9 (2 x ArCH), 98.3 (FcC), 72.4 (FCC), 72.2 (2 × FcCH), 70.6 (2 × FcCH), 65.6 (CH₃), 65.5 (2 × FcCH), 60.7 (2 × FcCH). Anal. Calc. for C₃₁H₂₇FeNO₁₁: C, 56.8; H, 4.52; N, 3.69. Found: C, 56.26; H, 4.61; N, 3.80. Crystal data for 7. C₃₁H₂₇FeNO₁₁. M_w = 397.20. Z = 1.0, monoclinic P 2₁/c, a = 14.7456(6), b = 7.4476(3), c = 17.2948(8) Å, β = 114.162(1)°. 

General procedure 2. Under argon, N-hydroxysuccinimide (1.5 equiv) and EDC.HCl (1.5 equiv) were added to a solution of the corresponding protected 1’-aminocarbonylferrocene-1-carboxylic acid (1.0 equiv) in anhydrous DCM (0.1 M). After 5h stirring at room temperature, volatiles were removed under vacuum to give the crude product. This was purified by column chromatography on silica, eluting with EtOAc/heptane (1:20) to give the title product as an orange solid.

2.5-Dioxopyrrolidin-1-yl 1’-(tert-butylicarbonyl)aminoferrocene-1-carboxylic acid (10). The general procedure 2 using 1’-(tert-
butylcarbonylamino)ferrocene-1-carboxylic acid (1, 345 mg, 1.0 mmol, 1.0 equiv), N-hydroxysuccinimide (172 mg, 1.5 mmol, 1.5 equiv) and EDC.HCl (287 mg, 1.5 mmol, 1.5 equiv) afforded the title product as an orange solid (276 mg, 62%) and 1H-NMR [500 MHz, CDCl₃] δ 6.36 (s, 2H, 2 x ArH), 4.82 (s, 4H, 4 x FcCH), 4.68 (s, 4H, 4 x FcCH), 4.56 (s, 4H, 4 x FcCH), 4.08 (s, 4H, 4 x FcCH), 1.43 (s, 18H, 2 x (CH₃)₃), 1.35 (C=O), 136.7 (ArC), 128.4 (2 x ArCH), 128.0 (ArCH), 127.9 (2 x C(CH₃)₃), 166.8 (C=Oester), 153.3 (C=Oester), 143.7 (2 x ArC), 140.8 (2 x ArCH), 127.6 (2 x ArCH), 127.0 (2 x ArCH), 125.0 (2 x ArCH), 120.1 (2 x ArCH), 99.2 (FcC), 74.9 (2 x (ArCH)₂), 70.7 (2 x FcCH), 69.9 (2 x FcCH), 65.2 (CH₂), 63.6 (FcC), 61.4 (2 x FcCH), 46.7 (CH₂), 25.4 (2 x CH₂) Anal. Calcd for C₅₃H₄₇F₂NO₅: C, 83.85; H, 5.49. Found: C, 83.75; H, 5.56.
