**21 ABSTRACT****22 Introduction**

23 Fusion imaging is a technique that facilitates endovascular navigation but is only available in  
24 hybrid rooms. The goal of this study was to evaluate the feasibility of fusion imaging with a  
25 mobile C-arm in a conventional operating room through the use of an angio-navigation  
26 station.

**27 Methods**

28 From May 2016 to June 2017, the study included all patients who underwent an aortic stent  
29 graft procedure in a conventional operating room with a mobile flat-panel detector (Cios  
30 Alpha, Siemens) connected to an angio-navigation station (EndoNaut, Therenva). The  
31 intention was to perform preoperative 3D CT/perioperative 2D fluoroscopy fusion imaging  
32 using an automatic registration process. Registration was considered successful when the  
33 software was able to correctly overlay preoperative 3D vascular structures onto the  
34 fluoroscopy image. For EVAR, contrast dose, operation and fluoroscopy time were compared  
35 to those of a control group drawn from the department's database who underwent a procedure  
36 with a C-arm image intensifier.

**37 Results**

38 The study included 54 patients and the procedures performed were: 49 EVAR, 2 TEVAR, 2  
39 IBD, 1 FEVAR. Of the 178 registrations that were initialised, it was possible to use the fusion  
40 imaging in 170 cases, i.e. a 95.5% success rate. In the EVAR comparison, there were no  
41 difference with the control group (n=103) for fluoroscopy time ( $21.9 \pm 12$  vs.  $19.5 \pm 13$  min,  
42  $p=0.27$ ), but less contrast agent was used in the group undergoing a procedure with the angio-  
43 navigation station ( $42.3 \pm 22$  ml vs.  $81.2 \pm 48$  ml,  $p<0.001$ ) and operation time was shorter  
44 ( $114 \pm 44$  vs.  $140.8 \pm 38$  min,  $p<0.0001$ ).

**45 Conclusion**

46 Fusion imaging is feasible with a mobile C-arm in a conventional operating room and thus  
47 represents an alternative to hybrid rooms. Its clinical benefits should be evaluated in a  
48 randomised series but our study already suggests that EVAR procedures might be facilitate  
49 with an angionavigation system.

## 53 **Introduction**

54 Fusion imaging is a technique used in vascular surgery in which a preoperative 3D CT scan is  
55 projected onto 2D fluoroscopy. This makes it possible to navigate the vascular tree without  
56 necessarily having to use iodinated contrast agent. An increasing number of studies are  
57 reporting on the use of fusion imaging in aortic endovascular procedures and its benefits(1-5).  
58 This imaging modality is however based on a certain number of prerequisites that limit the  
59 number of centres using it. These prerequisites are currently only fulfilled by floor-mounted  
60 fixed imaging systems that make automatic adjustments for movements of the operating table.  
61 Fusion imaging involves alignment (registration) of the preoperative CT scan with the  
62 fluoroscopy image. Once registration has been performed, whenever the table or C-arm  
63 moves the system is capable of realigning the preoperative CT scan with the 2D fluoroscopy  
64 image. In practice, only surgeons performing procedures in hybrid rooms have access to  
65 fusion imaging and other modern navigation tools. The cost of hybrid rooms is a major barrier  
66 to adoption of this technique.

67 The FUTUR study (whose French acronym stands for 'feasibility of computer-assisted aortic  
68 and iliac endovascular procedures with mobile C-arm') set out to overcome the challenge of  
69 performing fusion imaging with a mobile C-arm in a conventional operating room and  
70 making it compatible with the clinical workflow.

71

## 72 **Patients and Methods**

73 The protocol and informed consent form were approved by the local institutional review  
74 board, and all subjects gave informed consent.

75

### 76 *Study design*

77 The study was a single-centre, prospective, consecutive feasibility pilot study. The primary

78 objective was to evaluate the feasibility of fusion imaging during aortic endovascular  
79 procedures with a mobile C-arm through the use of the EndoNaut® angio-navigation station  
80 (Therenva; Rennes, France). Secondary objectives were to evaluate the efficiency of the  
81 system when deploying infrarenal aortic stent grafts to treat unruptured atheromatous  
82 aneurysms (EVAR).

83 The primary endpoint was the feasibility rate of fusion defined as the convergence of bone  
84 registration and the projection of the vascular 3D structure onto the fluoroscopy image  
85 (number of initialised registrations/number of convergent registrations). If the accuracy and  
86 robustness of the registration algorithm was already quantified in Duménil et al. (20), the  
87 convergence of the algorithm was qualitatively performed by visual inspection of the main  
88 angio-navigation system user solely. Registration failures were easily detectable even from a  
89 non-expert eye as the algorithm gave an aberrant solution to the registration problem.  
90 Secondary endpoints concerned radiation dose as measured by fluoroscopy time (FT in min),  
91 dose-area product (DAP in Gy.cm<sup>2</sup>) and air kerma (AK in mGy).

#### 92 93 *Inclusion criteria*

94 Patients eligible for endovascular treatment of aneurysm disease of the aorta.

95 Procedure performed in a conventional operating room equipped with a mobile flat-panel  
96 detector (30×30 cm) (Cios-Alpha, Siemens®, Munich, Germany) and a floating table.

97 Patients who received written and verbal information about the protocol and did not object to  
98 participating in the trial.

99

#### 100 *Non-inclusion criteria*

101 -Patients who also required a conventional surgical revascularisation procedure or who  
102 required an endovascular revascularisation procedure in another site.

- 103 -Patients who underwent MR angiography during preoperative evaluation.
- 104 -Non-analysable CT angiogram (no or poor injection).
- 105 -Procedure performed in a hybrid room or in an operating room not equipped with a mobile
- 106 flat-panel detector.

107

#### 108 *Fusion imaging principle and operation of EndoNaut® station*

109 The EndoNaut station is connected to the C-arm and retrieves the video signal generated by  
110 the C-arm (Fig. 1). The station is positioned in front of the surgeon and becomes his or her  
111 primary navigation interface. Sizing and planning data are derived from the preoperative  
112 analysis carried out with EndoSize® software (Therenva; Rennes, France) and transmitted to  
113 the station by importing a dedicated file from a USB storage device. The following data are  
114 exported from the sizing software: aortoiliac mesh with key points used for sizing represented  
115 as rings (below the lowest renal artery, iliac bifurcations – Fig. 1). All measurements and  
116 aortic 3D screenshots (reporting c-arm angulation) are also exported. Human-computer  
117 interaction is via a touch-sensitive tablet in one touch mode. Preoperative CT-scan is  
118 searchable during all the procedure thanks to the tablet which controls every “image action”  
119 (registration, navigation, measurements, numerical zoom...). To use fusion imaging  
120 functionality, the registration must be initialised after setting C-arm/operating table angulation  
121 as determined during preprocedural planning. The user then has to align, in an approximate  
122 manner and in only one view, the bone 3D volume of the preoperative CT scan with the 2D  
123 bony structures of the fluoroscopy image. Next, the software performs perfect, precise  
124 alignment of bony structures using rigid 3D/2D registration. The duration of this geometric  
125 transformation depends on the size of the image matrix and the C-arm used. For the C-arm  
126 used in the present study, the average duration was 15 +/- 3s and never exceeded 22 seconds.  
127 Each registration is valid until either the table or the C-arm position/angulation (i.e. C-arm

128 pose) changes. A new registration becomes mandatory in that cases, and on the contrary to  
129 fixed C-arm in hybrid room the fusion mask cannot be used to automatically position the table  
130 or the gantry. After completion of registration, the vascular tree is projected with the planning  
131 data defined using EndoSize®. Rings are visible in the planned deployment areas in the upper  
132 and lower landing zones (Fig. 2A). For tortuous anatomy, in order to anticipate anatomical  
133 deformations(6-8) caused by the extrastiff guidewire and the delivery system, a previously  
134 simulated deformed 3D model is projected (Fig. 2B). Several studies have specifically  
135 addressed simulation(9-11). These simulations are not carried out by the station but on a  
136 workstation dedicated to sizing and simulation. For TEVAR (thoracic stentgrafts), FEVAR  
137 (fenestrated stentgrafts) and IBD procedures (iliac branched device), rings are projected onto  
138 the planned landing zones and the ostia of target vessels (Fig. 3 and 4). The precision of the  
139 fusion in terms of location of target vessels (renal, internal iliac arteries) is always verified by  
140 injection of a small volume of iodinated contrast agent. If there is a misalignment of the  
141 projection of the 3D fusion mask and angiography due to the insertion of stiff guidewire,  
142 adjustments are made.

143

#### 144 *Control group*

145 For the EVAR procedures, contrast dose, fluoroscopy an operation time were compared to  
146 those of a control group of patients who received an aorto-bi-iliac stent graft for non-ruptured  
147 AAA using a mobile image intensifier system (OEC 9800, General Electric; GE, USA)  
148 without an angionavigation station. These patients were drawn from the local EVAR database  
149 and were operated upon between January 2013 and December 2014, the date on which the  
150 mobile flat-panel detector in the study came into use.

151

#### 152 *Statistical analysis*

153 Quantitative data are expressed as mean  $\pm$  standard deviation and qualitative data as a number  
154 and corresponding percentage. Data were compared using Student's t-test. Significance was  
155 set at  $p < 0.05$ .

156

ACCEPTED MANUSCRIPT

**157 Results***158 Patients and procedures*

159 From 1 May 2016 to 30 June 2017, 54 patients (49 men, 92.6%) of mean age  $73.4 \pm 9.3$  years  
160 were included in the study. Mean BMI was  $28.3 \pm 7.7$  kg/m<sup>2</sup>. The procedures performed  
161 were: 49 bifurcated stent grafts including 2 with unilateral internal iliac artery embolisation  
162 and one with an anchoring system (Aptus, Medtronic); 2 branched iliac; 2 thoracic; and 1  
163 fenestrated stent graft. The mean duration of the EVAR procedures was  $103.6 \pm 25.4$  min. In  
164 this cohort, proximal and distal seals were achieved with the successful introduction and  
165 deployment of the device in the absence of surgical conversion or mortality, type I or III  
166 endoleaks, or graft limb obstruction. Considering this definition, the technical success was  
167 100%. Percutaneous access was performed for 50 (92.6%) patients (bilateral) without open  
168 conversion by using 6 Fr Perclose Proglide device (Abbott Vascular, Redwood City, CA).  
169 Every percutaneous access was ultrasound-guided. Patients were deemed unfit for  
170 percutaneous access (n=4) when the majority of the anterior wall of the common femoral  
171 arteries were calcified.

172

*173 Primary endpoint*

174 The mean number of registrations initialised per patient was  $3.3 \pm 1.1$ . Of the 178  
175 registrations initialised across all patients, it was possible to project the vascular tree onto  
176 fluoroscopy in 170 cases, i.e. a feasibility rate of 95.5%. The feasibility rate seems to be  
177 similar for all procedure types (Table 1).

178

*179 Secondary endpoints and comparison with control group*

180 Table 1 shows the radiation and contrast dose for each procedure type. The control group  
181 consisted of 103 patients who underwent EVAR (Fig. 4). Demographic data are compared

182 between the EVAR group of the FUTUR study and the control group in the table 2. For  
183 radiation data, no significant difference between the groups was found. On the basis of  
184 comparable body mass indices, fluoroscopy time ( $21.9 \pm 12$  vs.  $19.5 \pm 13$  min,  $p=0.27$ ) and  
185 dose-area product ( $70.6 \pm 48$  vs.  $67.3 \pm 74$  Gy.cm<sup>2</sup>,  $p=0.77$ ) did not vary between the two  
186 groups. However, less contrast agent was used in the “FUTUR” group ( $42.3 \pm 22$  ml vs.  $81.2$   
187  $\pm 48$  ml,  $p<0.0001$ ).

188

## 189 **Discussion**

190 Herein we report what is to our knowledge the first use of software capable of performing 3D  
191 monomodal (CT)/2D fusion with a mobile C-arm for the placement of an aortic stent graft. In  
192 all series reporting the use of fusion imaging a fixed system has been necessary(1, 3, 12-19).  
193 The main reason is that the operating table has to be connected to the imaging system so that  
194 the latter can realign the preoperative CT scan with the fluoroscopy image whenever the table  
195 moves. In this regard, the system we report is not capable of realignment and this may  
196 constitute in itself a limitation. However, in routine practice, fusion imaging is only useful at  
197 very specific moments during placement of, for example, a bifurcated stent graft. During  
198 deployment of the main body, the angle of the C-arm has already been determined in advance,  
199 and the practitioner can focus on gradual deployment of the stents and needs to see the  
200 position of the renal arteries to perfectly position the stent graft. At this stage, there are no  
201 table or C-arm movements; on the contrary, good visualisation of the stent graft and aorta is  
202 required. This is also true during deployment of the iliac limbs, in order to ensure precise  
203 placement in relation to the internal iliac artery. During insertion of the guidewire, catheters  
204 or stent graft, and even during catheterisation of the contralateral stump, table movements are  
205 frequent, but projection of the vascular tree is not essential to the practitioner. So although the

206 software reported here requires that registration be repeated after every table movement, in  
207 our opinion this does not constitute a limitation in routine practice.

208 The technological challenge presented by fusion imaging with a mobile C-arm is to offer  
209 registration that is as fast as possible and above all only requires one 2D fluoroscopy view so  
210 that the system is compatible with the clinical workflow. The EndoNaut® station is the only  
211 software that uses only one 2D view to perform registration with the 3D CT scan, as has been  
212 previously reported(20). If the current system only uses information extracted from the pre-  
213 operative 3D CT scan, other types of imaging modalities (MRI, non-enhanced CT,  
214 ultrasound) could also be considered and is a subject of further improvement. The first  
215 publications for fusion imaging described systems that could only perform 3D/3D  
216 registration, which required CBCT at the start of the procedure(19, 21, 22). Given the  
217 radiation emitted by CBCT, systems evolved towards 3D/2D registration(3) that restricted  
218 CBCT to post-procedure assessment(23-26). Hence 2D fluoroscopy acquisition was necessary  
219 but 2 views were needed to achieve sufficient precision and this is no longer the case in the  
220 present study. With regard to the duration of the registration calculation, we did not report it  
221 in a quantitative manner because short duration is a prerequisite for studies such as the present  
222 one designed to demonstrate feasibility before envisaging studies to demonstrate clinical  
223 benefits. The reported results demonstrate that fusion imaging is feasible in the vast majority  
224 of EVAR cases. It was not feasible in cases with C-arm/operating table procedural  
225 angulations that were extreme for a conventional operating room. Beyond 35-40° inclination  
226 (regardless of orientation), the fluoroscopy image is contaminated by bony structures such as  
227 the upper limbs which are not visible on the CT scan and which jeopardize alignment of the  
228 two reference images. Nevertheless, this problem can be overcome by abducting and  
229 externally rotating the arms during the procedure, for example.

230 The majority of patients in our study underwent EVAR, as this is the predominant activity and  
231 it is also the procedure with the highest reproducibility. The other stent graft cases we  
232 reported are anecdotal and were mentioned in order to demonstrate that the station also works  
233 with other procedures. Similarly, we did not report cases of iliac recanalization or renal and  
234 mesenteric angioplasty, which are now systematically performed with the station.

235 Unsurprisingly, the radiation dose was not shown to be lower than in the control group. This  
236 finding must be interpreted with the utmost caution because the comparison involves  
237 completely different systems. The flat-panel detector does not use the same technology as an  
238 image intensifier, nor does it have the same physical characteristics, both factors that affect  
239 the delivered dose. Hence, drawing conclusions from this finding is fraught with bias.

240 Moreover, we are reporting the experience of one teaching hospital, one in which experienced  
241 senior practitioners, senior practitioners who have become independent more recently and  
242 junior practitioners under supervision participate in procedures. There is heterogeneity in the  
243 use of X-rays beyond adherence to ALARA principles. For example, a junior practitioner will  
244 attempt to track progress of the device through the aorta fluoroscopically, whereas a senior  
245 practitioner will insert the device "blindly". The real comparison for radiation dose and X-ray  
246 use would be a single-operator randomised series to overcome the anatomical differences  
247 between patients that give rise to procedural difficulties. In comparison to image intensifiers,  
248 flat-panel detectors offer higher image quality (more pixels per mm<sup>2</sup>), and the image matrix is  
249 larger, so a higher radiation dose could have been expected, but this was not the case.

250 On the other hand, when we consider use of contrast agent, there is a clear difference. And it  
251 is more logical to consider that the benefit is related to the station and not to the different  
252 characteristics of the C-arms used. As a reminder, in the series of Hertault et al.(3), use of a  
253 hybrid operating room did not lead to a significant reduction in the volume of contrast agent  
254 used for bifurcated stent grafts (only for fenestrated/branched stent grafts). In this series, the

255 X-ray dose reduction was very clear but it was comparing two different systems, hence it was  
256 not the fusion imaging that led to this reduction.

257 Finally, the recent meta-analysis by De Ruiter et al.(4) concluded: "For equivalent  
258 fluoroscopy times, the use of a fixed C-arm in noncomplex procedures leads to higher patient  
259 radiation doses compared to a mobile C-arm". We therefore believe that the combination of a  
260 mobile flat-panel detector with fusion imaging is a completely acceptable alternative to a  
261 hybrid operating room.

262

### 263 **Limitations**

264 In the present study, we did not report any quantitative criteria for fusion precision. Several  
265 publications(2, 6, 8, 12) have shown that, regardless of the registration method used, fusion  
266 precision is found to be lacking when compared to subtraction angiography. Maurel et al.(6)  
267 clearly showed, with the aid of perioperative CBCT, displacement of the ostia of renal and  
268 visceral arteries in different planes due to deformations caused by insertion of a rigid material  
269 (extrastiff guide, introducer) in the aorta. Several solutions have been considered to resolve  
270 this phenomenon, such as "Image-based tracking fusion system" approaches. We decided not  
271 to measure fusion precision here because currently no system is able to predict deformations  
272 in a very precise manner. Even in cases with non-tortuous anatomy, there may be a mismatch  
273 between the fused image and angiography, which in our opinion remains essential for  
274 validating the fusion (7 ml to 30 ml/s suffice at the proximal landing zone). As long as  
275 registration is based on bony structures (hence with rigid transformations), there will be a  
276 mismatch with arterial structures which by nature are soft and deformable, which therefore  
277 calls for approaches based on elastic registration(27), for example, or digital simulation  
278 approaches that predict deformations using a biomechanical model. We have already  
279 published several studies on this simulation approach(10, 11), which is integrated into the

280 planning and fusion software. The objective of the present study was not to test the precision  
281 of registration with a simulated and deformed model. A specific methodology, which was not  
282 possible nor envisaged in the study design, needs to be developed for this purpose (using,  
283 among others, perioperative CBCT). Moreover, we have already quantified the accuracy and  
284 robustness of the registration algorithm in the dedicated methodological article presenting the  
285 detailed principle of the 3d/2d registration (20). In this already published paper, a thorough  
286 and precise validation scheme was proposed, and the mean registration error on the bony  
287 landmarks was found to be  $< 0.5\text{mm}$ . Finally, the learning curve of the team and the fact that  
288 we are a training center can lead to a bias in the reproducibility of the results and the  
289 efficiency in the EVAR procedures. In this study, there was investigators with different  
290 experiences (range from 10 to 300 EVAR procedures) but subgroups would not give enough  
291 statistical power to reach statistical differences in radiation parameters.

292

### 293 **Conclusion**

294 Fusion of the 3D preoperative CT scan with 2D fluoroscopy is possible with a mobile C-arm  
295 and compatible with the clinical workflow. In addition to the unquantifiable visual comfort  
296 and the possibility of using all modern navigation tools, this technique also appears to reduce  
297 the volume of contrast agent for EVAR procedures. The combination of a mobile flat-panel  
298 detector with a computer-assisted surgery station is an acceptable alternative to hybrid  
299 operating rooms for complex aortic procedures with high-performance imaging.

**401 Legends for figures and tables**

402

403 Fig. 1: The angio-navigation station is placed in front of the surgeon (black arrow), who  
404 interacts with it via a remote touch-sensitive tablet (white arrow) providing all image-related  
405 actions (zoom, registration, CT scan interpretation, etc.). Screens of the c-arm are placed on  
406 the right (yellow arrow).

407

408 Fig. 2: Fusion of preoperative CT scan for EVAR using a non-deformed model (A), which is  
409 nullified by deformations caused by rigid tools. Adjustment of the fused image (B) by  
410 projection of a model deformed by digital simulation.

411

412 Fig. 3: Regardless of the procedure, low-volume angiography is systematically performed to  
413 verify the position of renal arteries in FEVAR procedures for example (A). The prosthesis is  
414 deployed under fusion imaging guidance (B) and catheterisation is performed without the  
415 roadmap (C).

416

417 Fig. 4: For TEVAR procedures in the descending thoracic artery, the prosthesis is deployed  
418 frontally (A). A ring is projected onto the distal landing zone and the coeliac trunk (B-C).  
419 This avoids a procedure with the C-arm sideways, which would increase the radiation dose to  
420 the operator.

421

422 Fig. 5: Box plots comparing variables of patients operated on with the angio-navigation  
423 station and the control group.

424

425

Table 1: Fusion feasibility rate and contrast and radiation dose by procedure type

	Registration success	Contrast agent (mL)	Fluoroscopy time (min)	DAP (Gy.cm <sup>2</sup> )	AK (mGy)
EVAR (n=49)	95.1% (155/163)	41.9 ± 23.1	21.6 ± 12.3	70.9 ± 48.2	254.2 ± 161.5
TEVAR (n=2)	100% (4/4)	23.8	6	20	79
IBD (n=2)	100% (6/6)	39.8	39.8	67.7	363.5
FEVAR (n=1)	100% (5/5)	65	38	163.1	603

\* DAP = Dose-area product, AK = Air kerma

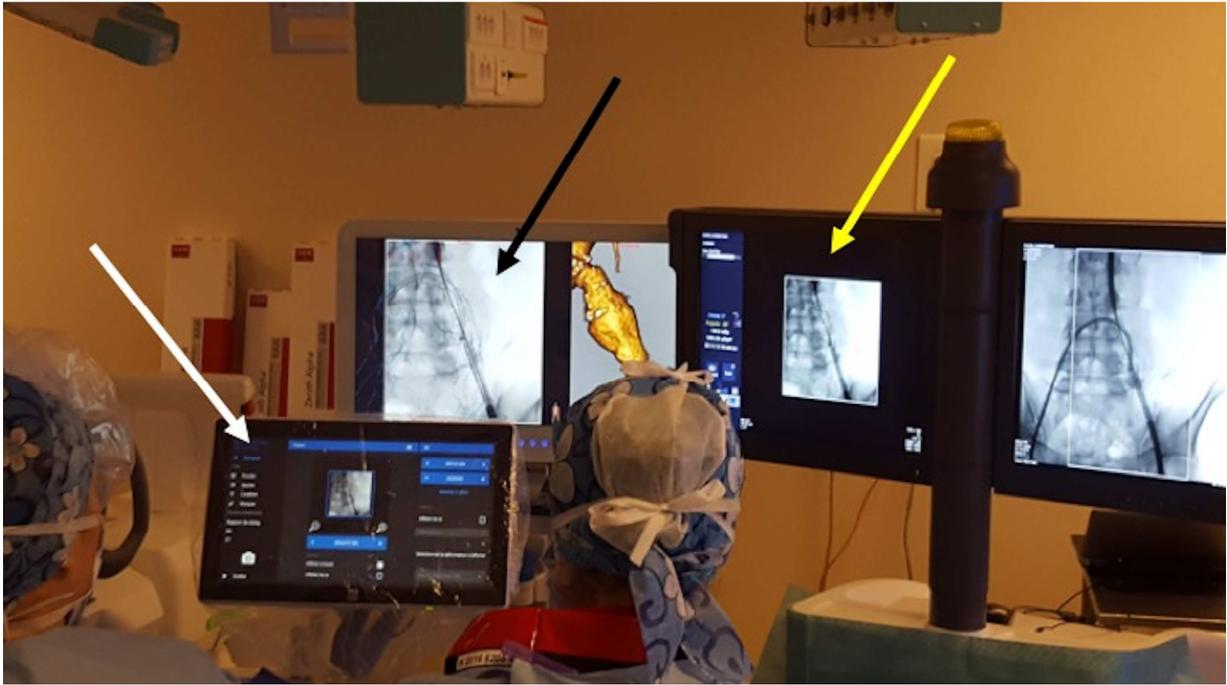

Table 2

	EVAR Fusion (n=49)	EVAR No fusion (n=103)	<i>P</i> value
Age (years; mean ± SD)	73.7 ± 9.3	73.9 ± 9	0.89
Gender (Male)	44 (89.8%)	97 (94.2%)	0.26
BMI (kg/m <sup>2</sup> )	28.3 ± 5	26.9 ± 4	0.19
Symptomatic PAD*	0 (0%)	4 (3.8%)	0.21
Coronary artery lesions	12 (24.5%)	28 (27.2%)	0.84
Severe respiratory failure	1 (2%)	4 (3.9%)	0.48
Renal failure (eGFR<30)**	2 (4.1%)	6 (5.8%)	0.49
Treated hypertension	30 (61.2%)	82 (79.2%)	0.06
History of tobacco	36 (73.5%)	75 (72.8%)	0.9
Diabetes	6 (12.2%)	7 (6.8%)	0.53
Treated dyslipidemia	35 (71.4%)	64 (62.1%)	0.53
Anticoagulant therapy	3 (6.1%)	4 (3.9%)	0.41

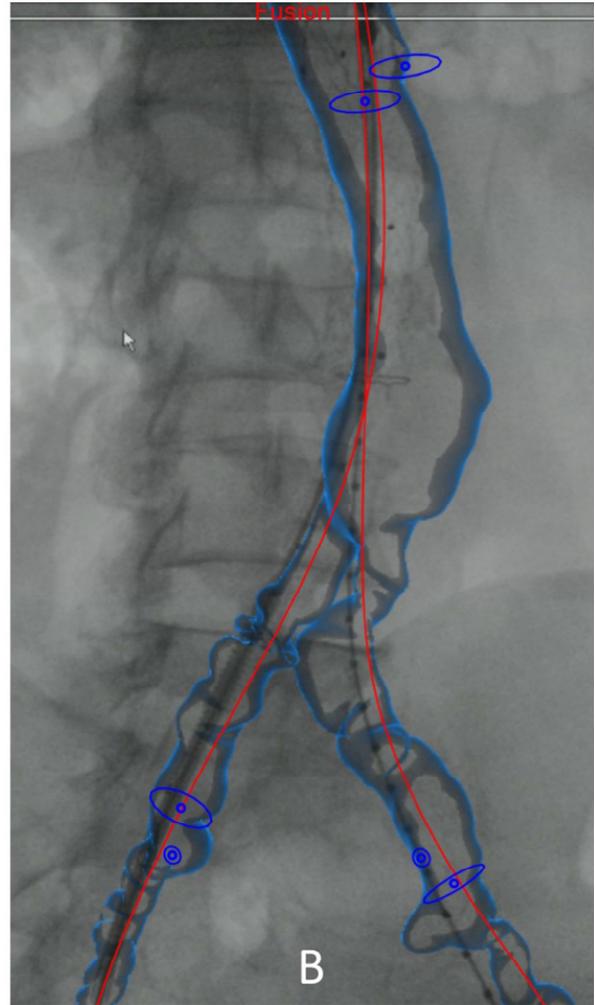

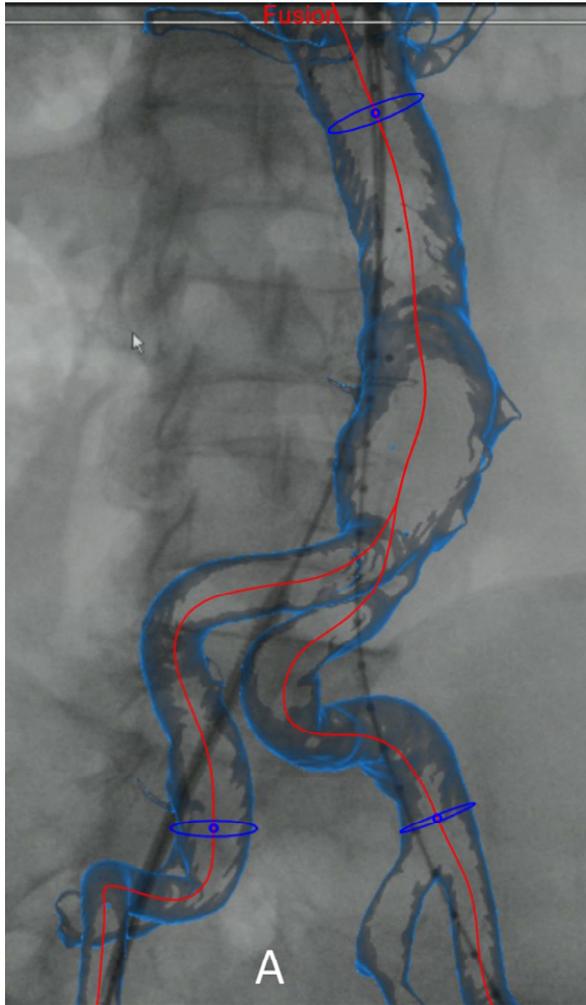

\* Peripheral Arterial Disease

\*\*Estimated Glomerular filtration Rate in ml/min/1.73m<sup>2</sup>
