Abstract

Single crystals of a new hybrid metal halide $[C_7H_{16}N_2][CuCl_4]$ were grown by hydrothermal technique and characterized by single-crystal X-ray diffraction, IR and Raman spectroscopy, optical absorption, differential scanning calorimetry and dielectric measurements. The compound $[C_7H_{16}N_2][CuCl_4]$ crystallizes in the monoclinic space group $P2_1/c$ at room temperature. In the molecular structure, the tetrachlorocuprate anions are linked to the organic cations through $N-H \cdots Cl$ hydrogen bonds. The Raman and IR analyses confirm the presence of the organic groups and the anionic entities. UV-Visible absorption spectrum revealed the energy of the optical band gap. The DSC measurements indicated that $[C_7H_{16}N_2][CuCl_4]$ underwent two sequential phase transitions at around 288 and 388 K. The temperature dependence of the electrical conductivity confirmed the phase transitions that were well detected with differential scanning calorimetry. The analysis of Nyquist plots revealed the contribution of the bulk mechanism and the grain boundaries.

Keywords: *Crystal structure, Hybrid metal halide, Optical band gap, Phase transitions, Electrical properties, Conduction mechanism.*

1. Introduction

In the past decade, a great attention has been devoted to the family of hybrid metal halides thanks to their potential applications in the fields of magnetism [1-3], ferroelectrics and electrical properties [4-8], optoelectronics and memory devices [9-11]. These types of materials have also received much attention owing their interesting molecular shapes. Moreover, the hybrid compounds have stimulated modern-day materials science research due to their innumerable characteristics such as flexibility, specific structural architectures and potential phase transition materials [12-13]. Actually, inorganic-organic phase transition materials with formula AMX_4 have been synthesized, in which M is a metal cation that coordinated by four (X) anions to form an AX_4 tetrahedron, and A is a organic cation. Especially, metal-halide compounds including 2-methylpiperazine, 1,4-diazabicyclo [2.2.2] octane and quinuclidine have made further progress [14-20]. For example, [quinuclidinium][ReO_4][16-17]; ($H_2dabco-C_2H_5$)[MCl_4] [20] and ($H_2dabco-CH_2-Cl$)[MCl_4] [19] contain an independent organic cations and a discrete $[MX_4]^{n-}$ (M = Co, Zn) anions. Quinuclidinium perrhenate (I) compound, exhibits ferroelectricity above room temperature, polarization rotation and undergoes a phase transition to a plastic crystal phase at a higher temperature [17]. Eventually, these hybrid materials containing quinuclidine (1-azabicyclo[2.2.2]octane) or its derivatives as templating agents has led to the preparation of some materials with interesting physical properties such as a switchable polarity, ferroelectricity, piezoelectricity, second-harmonic generation (SHG), luminescence and optical activity [16, 21-22]. Herein, 3-aminoquinuclidine as the derivative of dabco, was protonated and combined with metal halides, forming a new hybrid compound $[C_7H_{16}N_2][CuCl_4]$. In this paper we present the structural characterization, optical studies, differential scanning calorimetric analysis, electric and dielectric measurements as a function of temperature.

2. Experimental section

2.1. Materials

Copper(II) chloride ($CuCl_2$), hydrochloric acid (HCl; 37%), 3-aminoquinuclidine dihydrochloride were purchased from Sigma-Aldrich and used without further purification.

2.2. Synthesis

The synthesis of 3-aminoquinuclidinediium tetrachlorocuprate(II) complex was carried out in home-built Teflon-lined stainless steel pressure bombs of 120 mL maximum capacity. 1 mmol of $CuCl_2$ and 2 mmol of 3-aminoquinuclidine dihydrochloride were dissolved together in 20 mL of deionized water and hydrochloric acid. The mixture was placed in a Teflon-lined autoclave that was then sealed and heated to 120°C for 2 days. It was then allowed to cool to room temperature in a cold water bath. Autoclaves were opened in air, and products were recovered through filtration. Orange stick-shaped crystals with suitable dimensions for crystallographic study were recovered.

The crystals were washed several times with distilled water and dried in open air. Reaction yields ranged between 60-79% based on Cu.

2.3. Single-crystal data collection and structure determination

Suitable crystals were mounted on an APEX II AXS-Bruker area detector 4-circles diffractometer. Intensity data sets were collected using Mo K α radiation ($\lambda = 0.71073$ Å) through the Bruker AXS APEX2 Software Suite [23]. Frame integration and data reduction were carried out with the program SAINT [24]. The program SADABS [25] was then employed for multiscan-type absorption corrections. The crystal structure was solved in the monoclinic symmetry, space group $P2_1/c$, according to the automated search for space group available in WinGX [26]. Copper and chloride atoms were located using the direct methods with the program SIR-2014 [27]. C and N atoms from the amine were found from successive difference Fourier calculations using SHELXL-2014 [28]. Their positions were validated from geometrical considerations as well as from the examination of possible hydrogen bonds. H atoms were positioned geometrically and allowed to ride on their parent atoms, with C–H = 0.97 Å and N–H = 0.89 Å. When the nitrogen is the protonated tertiary one, N(2) and N(4), the distance is fixed to 0.98 Å. Structure drawings have been made with Olex2 [29] program. Crystallographic data are given in Table 1.

2.4. Spectroscopies studies

The Raman spectra were excited by the 514.5 nm wavelength radiation of an Ar/Kr laser, and collected with a T64000 Raman spectrometer in the 180–3500 cm⁻¹ range. The spectrum was collected in all polarizations, but only the obtained in the Z(XX)Z polarization is presented with regard to their best signal-to-noise ratio.

IR absorption spectrum of the crystallized powders in KBr was recorded on a Perkin- Elmer FT-IR 1000 spectrometer in the 400–4000 cm⁻¹ range.

Optical properties are measured at room temperature using a Shimadzu-type 3101PC UV spectrophotometer that has a dual-beam monochromator, covers a spectrum from 200 nm to 2400 nm and uses two sources: (i) Xenon lamp for the UV-Visible domain, (ii) Halogen lamp for the infrared range. This technique makes it possible to determine the absorbance (A) and the reflectance (R). The optical absorption spectrum of the [C₇H₁₆N₂][CuCl₄] compound was recorded at room temperature in powder used in the form of films.

2.5. Thermal measurements

TGA measurements were performed on raw powders with a TGA ‘SETSYS Evolution’ under an N₂ atmosphere of [C₇H₁₆N₂][CuCl₄]. The thermogram was collected on 12.5 mg sample in the RT-873K range (heating rate of 5°C/min).

DSC measurements were recorded on raw powders with NETZSCH DSC 200 F3 instrument (Pt crucibles, Al₂O₃ as a reference) under nitrogen atmosphere. The thermograms were collected on 8 mg sample in the temperature range from 258 to 423 K with heating and cooling rate of 5 °C/min.

2.6. Impedance spectroscopy

The electrical measurements of the real and imaginary components of the impedance parameters (Z' and Z'') were measured on pellet disks of about 8 mm in diameter and 1.2 mm in thickness in the frequency range of 1–10⁶ Hz, with the SOLARTRON SI 1260 impedance coupled to a dielectric interface 1296 in the temperature range of 273–430K.

3. Results and discussion

3.1. Crystal Structure

The structure of [C₇H₁₆N₂][CuCl₄] compound was determined by X-ray diffraction analysis. At room temperature, data were consistent with the monoclinic space group $P2_1/c$, with unit cell parameters $a = 21.4852(1)$ Å, $b = 7.3367(3)$ Å, $c = 17.1508(8)$ Å, $\beta = 105.865(2)^\circ$ and $Z = 4$. The asymmetric unit consists of discrete [CuCl₄]²⁻ anions and two symmetrically independent [C₇H₁₆N₂]²⁺ cations (Figure 1). The [CuCl₄]²⁻ complexes anions adopt intermediate geometry between square-planar and regular tetrahedra with Cu-Cl bond distances ranging from 2.2123(9) Å to 2.2708(9) Å in [Cu₁Cl₄]²⁻ and from 2.2211(1) to 2.2654(8) Å in [Cu₂Cl₄]²⁻. Meanwhile, the Cl-Cu-Cl bond angles range between 96.58 (3) and 135.39 (4)° for [Cu₁Cl₄]²⁻ and between 98.07 (3) and 130.34 (4)° for [Cu₂Cl₄]²⁻, which are seriously deviated from the ideal values of 109.5° (Table 2). A description of the distortion from tetrahedral geometry has been evaluated by the Muetterties and Guggenberger method [$\Delta D = 0$ for a regular tetrahedron and $\Delta D = 100$ for a square-planar (D_{4h}) geometry]. The calculated ΔD (%) parameters for [Cu₁Cl₄]²⁻ and [Cu₂Cl₄]²⁻ are 26.8 % and 27.5 %, respectively. Therefore, the coordination geometry around the Cu^{II} ion can be described as a distorted tetrahedron. The geometrical features of CuCl₄ entities agree well with those reported for other Cu(II) salts containing isolated tetrahedra [31, 32]. In the case of the [C₇H₁₆N₂]²⁺ cation, the selected bond lengths and angles fall within the normal ranges. Indeed, the N-C, C-C distances and the N-C-C, C-N-C, C-C-C angles are comparable with those observed in other similar hybrid metal-halides with the same organic cation [33, 34]. The crystal structure is stabilized by intermolecular hydrogen-bonding interactions leading to layers that are parallel to b and c axes (Figure 2). Within the intermolecular bonds, the distances of N...Cl interactions fall in the range of 3.227(3) - 3.448(3) Å, and the angles range from 130 to 157°. The hydrogen bond parameters are given in Table 3. The hydrogen bonds connect the cations and anions play a significant role in the formation of three-dimensional frameworks and stabilizing the supramolecular structure.

3.2. Vibrational frequencies

Raman and IR complementary techniques are used to identify the presence of all molecular groups for the synthesized compound. These spectra are recorded in Figure 3 (a) and (b). The Raman spectrum shows three frequency regions: the first under 350 cm^{-1} corresponding to the Cu-Cl vibration modes and indicates the presence of the CuCl_4^{2-} anion, the second region between 383 and 1570 cm^{-1} corresponds to the NC_4 , CH_2 , NH_3 and C-N-H vibrations modes, the third region above the 2900 cm^{-1} indicate the C-H stretching vibration. All vibrations modes of the organic cation above 383 cm^{-1} appears with a small difference in frequency in the IR spectrum. This result confirms the presence of the inorganic and organic entities proved by the X-ray diffraction analysis. Table S1 (See Supporting Information) lists the corresponding calculated modes of such observed peaks.

3.3. Optical energy gap analysis of $[\text{C}_7\text{H}_{16}\text{N}_2][\text{CuCl}_4]$

UV-visible optical absorption spectrum of the $[\text{C}_7\text{H}_{16}\text{N}_2][\text{CuCl}_4]$ shows the presence of three bands (Figure 4). The strong band noticed around 287 nm is ascribed to the excitation of an electron from the valence band to the conduction band in the $[\text{CuCl}_4]^{2-}$ tetrahedron, indicating the gap of this material. The valence and conduction bands are represented by the orbital (3p) of copper and (3p) of Cl, respectively [35]. Absorption band at 400 nm may be due to excitonic absorption in the band gap. The band observed at 683 nm corresponds to an emission band in the visible red spectral range. Based on the Tauc's expression [36], we have deduced the gap energy for the direct and indirect transition by the extrapolation of the linear part of the curve (Figure 5) with the energy axis. The direct and indirect gap energy values are 4.61 eV and 3.52 eV, respectively.

It is trustworthy to mention that the discreet variation in the angular distortions correlates well with the materials band gap, as revealed by UV-vis spectroscopy [37-40]. The determination of the band gap energy is realized by the distortion of the inorganic parts. The supporting distortion and shrinkage of $[\text{CuCl}_4]^{2-}$ coordination lead to a considerable band gap tightening, which is of fundamental significance for the optoelectronics applications. Furthermore, the length and shape of the organic part may have an impact on the structure and band gap behaviors, which is the new vision for the organic-inorganic-like materials. Essentially, the band gap of $[\text{C}_7\text{H}_{16}\text{N}_2][\text{CuCl}_4]$ is smaller than the calculated values of the direct band gaps found in the three compounds $[(\text{CH}_3)_3\text{NH}][\text{CdCl}_3]$ (5.41 and 5.30 eV) [40] ; $[\text{N}(\text{CH}_3)_4]_2[\text{CoCl}_4]$ (4.65 and 4.66 eV) [41] and $[\text{N}(\text{CH}_3)_4]_2[\text{MnCl}_4]$ (5.35 and 5.38 eV) [41], respectively. Hence, the calculated value of the title compound may be categorized as semiconductor material.

3.4. Thermal behavior

TGA and DSC measurements were carried out to highlight the phase transitions and the thermal stability of the compound. The TG thermogram shows that the compound seems to be stable up to

453 K. Above this temperature, a gradual weight loss appears at 460 K and that is considered like a limit of thermal stability of the compound (Figure 6). The transformation occurs in the temperature range 463–623K. The weight loss can be attributed to the decomposition of the amine group together with the chloride is removed to support the charge neutrality and corresponds to the formation of CuCl_2 (observed weight loss, 60.51%, theoretical, 59.71%). A similar decomposition has been observed in other hybrid-halide compounds [5, 20, 32].

DSC thermograms were recorded on heating and cooling (Figure 7) in the temperature range between 258 and 423 K. This study shows two sequential phase transitions on heating, the first of which is weak at $T_1=288\text{K}$ and the second is intense at $T_2=388\text{K}$.

3.5. Electrical properties

3.5.1. Impedance spectroscopy

The illustration of the impedance data in the complex plane permits the determination of the various contributions in the material, as the grain, grain boundary, and electrode contribution. Figure 8 shows the Nyquist diagram measured at several temperatures. All these plots are characterized by two semi-circles and a tail at lower frequencies, revealing the existence of three contributions. Indeed, the first one detected at high frequency describes the grain contribution, while the second is due to grain boundary one and the third at low frequency is due to the electrode response. The radius of the arc corresponding to the bulk resistance of the sample decreases with the increase of temperature, showing an activated thermal conduction mechanism. These diagrams are modeled with an equivalent circuit using the Z-VIEW software $((R_g//C)+(R_{jg}/CPE)+CPE)$ where R_g and R_{jg} the resistance of grains and grain boundaries, respectively, C and CPE the capacitance and capacity of the fractal interface, respectively. In order to substantiate the choice of equivalent circuit, we simulate the variation of Z' and Z'' as a function of frequency with the obtained parameters by the Z-VIEW software. The good matching between the experimental and calculated curves highlights that this equivalent circuit is well described the electrical behavior of this compound (Figure 9).

The conductivity σ_g is obtained from (R_p) by means of the relation:

$$\sigma_g = \frac{e}{R \cdot S}$$

where R_g is the bulk resistance obtained from the intercept of the semicircular arcs, observed at higher frequency, on the real axis (Z') and (e/S) represents the sample geometrical ratio. The temperature dependence of the conductivity σ_g is showed in Figure 10. This variation is described by three slope changes, thus confirming the two-phase transitions observed in the calorimetric study and revealing the existence of four phases, of which three are described by the Arrhenius law. The change of slope at $T=373\text{K}$ is due to the evaporation of water in this material; which indicates that phase II between 300K and 373K is not described by the Arrhenius law. This

material shows the hygroscopic character that influenced the variation of the conductivity. The calculated activation energy from linear fits to the data points of the described phases by the Arrhenius law are: $E_I = 0.08\text{eV}$, $E_{III} = 0.15\text{ eV}$ and $E_{IV} = 1.45\text{eV}$.

3.5.2. Modulus study

Figure 11 presents two peaks of M'' versus frequency. While the most intense peaks are associated with the grain effects (these peaks shift toward higher angular frequencies with the increase in temperature), the others are associated with the effects of grain boundaries, which confirms the observed result in the impedance spectra. These spectra of modulus M'' are fitted with the approximate frequency representation of the Kohlrausch–Williams–Watts (KWW) function, proposed by Bergman [42]:

$$M'' = \frac{M_1''_{\max}}{(1-\beta_1) + \frac{\beta_1}{1+\beta_1} \left[\beta_1 \left(\frac{\omega_{\max}}{\omega} \right) + \left(\frac{\omega}{\omega_{\max}} \right)^{\beta_1} \right]} + \frac{M_2''_{\max}}{(1-\beta_2) + \frac{\beta_2}{1+\beta_2} \left[\beta_2 \left(\frac{\omega_{2\max}}{\omega} \right) + \left(\frac{\omega}{\omega_{2\max}} \right)^{\beta_2} \right]}$$

where $M''_{\max}$ and $\omega_{\max}$ are the modulus maximum and the frequency at which M'' maximum, respectively.

The fitted value of $\omega_{\max}$ allows to deduce the $f_{\max}$, which is plotted in the Figure 12. This variation is given by the relation: $f_{\max} = A \exp(-E_a/(kT))$; where A is the pre-exponential factor, E_a is the activation energy and k is the Boltzmann's constant. The variation of $f_{\max}$ confirms the temperature transitions discovered in the calorimetric study, in which a modification of the slope curve is observed near each transition. Phases I, III and IV are well described by the Arrhenius relation. The determined activation energy in each phase is: $E_I=0.48\text{eV}$, $E_{III}=0.27\text{eV}$ and $E_{IV}=2.08\text{eV}$.

3.5.3. AC-conductivity and conduction mechanism

As shown in Figure 13, AC conductivity versus frequency at various temperatures of the sample under investigation displays independent-dc plateau at lower frequencies and frequency dependent-ac dispersion region at higher frequencies, which exhibits the distinctive behavior of the compound conductivity. This dependence of conductivity on frequency or so-called universal dynamic response of conductivity is related by a simple expression given by Jonscher's power law: [43, 44].

$$\sigma_{AC} = \sigma_{dc} + A\omega^s$$

where σ_{AC} is the ac conductivity, σ_{dc} is the direct current conductivity, A is a pre-exponential constant, $\omega = 2\pi f$ is the angular frequency and S lying between 0 and 1 is the power law exponent that implies the degree of interaction between the charge carriers and the lattice [45, 46]. The spectra of Ac conductivity as a function of frequency are thermally activated, increasing with the increase in temperature (Figure 13). The simulate Ac conductivity spectra based on the Jonscher's power law allows the determination of the direct current conductivity, pre-exponential constant A and the exponent S . The variation of the σ_{dc} conductivity as a function of temperature (Figure 14) show Arrhenius-type behavior in phases I, III and IV, which reveals a change of the curve slope at the two transitions phases observed in the calorimetric study and asserts the obtained result in the variation of σ_g . The activation energy calculated from linear fit to the data points is $E_I = 0.15$ eV, $E_{III} = 0.35$ eV and $E_{IV} = 1.24$ eV.

The values of the activation energies obtained from the analysis of equivalent circuit, modulus, and conductivity data are diverse. These results indicate that the transport is not through ion hopping mechanism in the investigated sample [47]. In fact, the conduction mechanism of our sample is linked by the variation of exponent S as a function of temperature. Different models have been considered in the literature based on two distinct processes: classical hopping over a barrier and quantum-mechanical tunneling, or combination of the two. These models are interconnected with the temperature variation (Figure 15) and a slope change near each transition specifies all phase transitions. According to this variation, the NSPT model can properly describe phases I and II, in which the values of (S) increase with the increase in temperature [48, 49]. In the overlapping large polaron tunneling OLPT model, the exponent S depends on both temperature and frequencies. Indeed, it decreases with the increase in temperature to a minimum value, and then augments when the temperature rises. This behavior can describe phase IV [50].

4. Conclusion

In summary, we successfully synthesized a low-dimensional hybrid copper halide, namely $[C_7H_{16}N_2][CuCl_4]$, by a facile hydrothermal method, which exhibits two sequential phase transitions at about 288 and 388K, being confirmed by the DSC measurements together with dielectric anomalies. The compound crystallizes in the monoclinic system, space group $P2_1/c$ with $Z = 4$. The cationic $[C_7H_{16}N_2]^{2+}$ and anionic $[CuCl_4]^{2-}$ entities are linked with each other by N-H...Cl hydrogen bonding to generate an interesting 3D supramolecular framework. The optical properties at the absorption edge of $[C_7H_{16}N_2][CuCl_4]$ showed three distinct peaks at 287, 400 and 683 nm, respectively. The value of the gap energy (E_g) is 4.61 eV. The equivalent circuit was determined and the impedance studies have clearly revealed the contributions of grain and grain boundary to the conduction process in the compound.

Appendix

Supplementary crystallographic data for this article in CIF format are available as Electronic Supplementary Publication from Cambridge Crystallographic Data Centre (CCDC 1553896). Table captions**Table 1:** Crystallographic data and structure refinement parameters for $[C_7H_{16}N_2][CuCl_4]$.**Table 2:** Selected bond distances (Å) and angles (°) in $[C_7H_{16}N_2][CuCl_4]$.**Table 3:** Hydrogen-bonding geometry (Å, °) for $[C_7H_{16}N_2][CuCl_4]$.**Table 1:** Crystallographic data and structure refinement parameters for $[C_7H_{16}N_2][CuCl_4]$.

Empirical formula	$C_7H_{16}N_2Cl_4Cu$
Formula weight ($g \cdot mol^{-1}$)	333.57
Temperature (K)	296
Crystal system	Monoclinic
Space group	$P2_1/c$
a (Å)	21.4852(1)
b (Å)	7.3367(3)
c (Å)	17.1508(8)
α (°)	90
β (°)	105.865(2)
γ (°)	90
V (Å ³)	2600.5(2)
Z	4
λ (MoK α) (Å)	0.71073
ρ_{cal} ($g \cdot cm^{-3}$)	1.704
Absorption correction	Multi-scan
μ (mm^{-1})	2.468
Crystal size (mm^3)	$0.59 \times 0.21 \times 0.17$
Crystal color/shape	Stick orange
hkl range	$-27 \leq h \leq 24$; $-9 \leq k \leq 9$; $-16 \leq l \leq 22$
θ range for data collection (deg)	$0.994 - 27.506$
Refinement method	Full-matrix least-squares on F^2
No. of collected reflections	18210
No. of independent reflections	5949
Observed reflections / restraints / parameters	4454 / 0 / 253
R_{int}	0.0378
$F(000)$	1352
Goodness of fit	1.030
Transmission factors	$T_{min} = 0.542$, $T_{max} = 0.657$
R indices	$R_1 = 0.0377$, $wR_2 = 0.0906$
Largest difference map hole ($e \text{ Å}^{-3}$)	$\Delta\rho_{max} = 0.74$, $\Delta\rho_{min} = -0.68$

Table 2: Selected bond distances (Å) and angles (°) for [C₇H₁₆N₂][CuCl₄].

Cu1–Cl1	2.2709 (9)	Cu2–Cl5	2.2307 (9)
Cu1–Cl2	2.2529 (8)	Cu2–Cl6	2.2653 (9)
Cu1–Cl3	2.2553 (9)	Cu2–Cl7	2.2213 (10)
Cu1–Cl4	2.2122 (9)	Cu2–Cl8	2.2462 (9)
Cl4–Cu1–Cl2	135.39 (4)	Cl7–Cu2–Cl5	99.83 (4)
Cl4–Cu1–Cl3	100.07 (4)	Cl7–Cu2–Cl8	103.36 (4)
Cl2–Cu1–Cl3	96.58 (3)	Cl5–Cu2–Cl8	130.15 (4)
Cl4–Cu1–Cl1	100.64 (3)	Cl7–Cu2–Cl6	130.34 (4)
Cl2–Cu1–Cl1	97.44 (3)	Cl5–Cu2–Cl6	99.44 (3)
Cl3–Cu1–Cl1	132.98 (4)	Cl8–Cu2–Cl6	98.07 (3)
ΔD (%) = 26.8		ΔD (%) = 27.5	

ΔD (%) : Muetterties distortion from the tetrahedron

ΔD (%) was calculated according to: ΔD (%) = $(1/n) \sum_j (|\Sigma_i (\delta_i - \delta_{ji})| / (|\delta_{j1} - \delta_{j2}|) \times 100$, where δ_i is the experimental dihedral angle and δ_{j1} and δ_{j2} are the theoretical dihedral angles for T_d and D_{4h} , respectively, and $n = 1 - 6$ are the six bond angles around the metal.

Table 3: Hydrogen-bonding geometry (Å, °) for [C₇H₁₆N₂][CuCl₄].

D–H...A	D–H	H...A	D...A	D–H...A

Highlights

- Novel organic-inorganic Copper (II) Halide was prepared and characterized by different techniques.
- Single-crystal X-ray studies confirmed the H-bonded network
- Optical study was investigated by the methods of UV-Vis absorption
- Differential scanning calorimetric shows several phase transitions.
- Electrical conductivity confirms the phase transitions detected well with DSC analysis.
