Abstract

In this work we report the synthesis of the cadmium(II)-*meso*-tetra(*para*-chloro-phenyl)porphyrin with the morpholine *O*-donor axial ligand with formula [Cd(TCIPP)(morph)] (**I**). This coordination compound adopts a distorted five-coordinate square pyramidal geometry indicated by a major *doming*, a moderate *ruffling* and *saddle* distortions of the porphyrinato core. The supramolecular architecture is dominated by intermolecular N–H···Cl and C–H···Cl interactions formed between the morpholine and the chlorine atom of the adjacent *meso*-phenylporphyrin of complex (**I**). Hirshfeld surface analysis was carried out to understand the nature of intermolecular contacts, where the fingerprint plot provides the information about the percentage contribution. UV-visible spectroscopy study highlighted the red-shift of the absorption bands after the insertion of Cd(II) metal ion into TCIPP moiety and after coordination of the morpholine axial ligand. Fluorescence emission spectroscopy study showed a remarkable blue-shift effect of the Q bands followed by a dramatical diminution of the fluorescence intensity, quantum yield (ϕ_f) and lifetime (τ_f) as consequence of the high quenching effect of the cadmium heavy metal and the distortion of the porphyrin core, which promotes the loss of the “motion energy” by other non-radiative energy dissipation processes than light emission. An increase of the singlet oxygen quantum yield (Φ_Δ) is also observed due to the heavy atom effect of cadmium(II) cation. The cyclic voltammetry investigation of the free base H₂TCIPP, the starting material [Cd(TCIPP)] and the Cd(II)-morpholine porphyrin species (**I**) is also reported.

Keywords: Cadmium(II) porphyrin coordination compound, X-ray crystal structure, Hirshfeld surfaces, Fluorescence, Singlet Oxygen, .

1. Introduction

The chemistry of porphyrins and related compounds dates back to the late nineteenth century. The porphyrin species and metalloporphyrins complexes are currently used in a variety of applications such as photodynamic therapy, [1-3] optoelectronics, [4-5] chemical sensors, [6] catalysis, [7] and photovoltaic systems [8]. Much of the excitement in porphyrin research lies in their modular and relatively facile synthesis, large size, ready dissolution in organic solvents, characteristic colors, rigidity, thermal stability, and affinity for metallation [9]. Since the middle of the last century, cadmium porphyrins have been studied and the physical and chemical properties of Cd-porphyrin derivatives have been of general interest. Cadmium(II) ion is too big to fit co-planarly into the cavity of porphyrin, it is located out of the ligand plane and distorts it. Therefore the structure deformation of cadmium(II) metalloporphyrins results in kinetic lability as well as peculiar photophysical and photochemical behavior [10-11]. By the other hand, both cadmium and porphyrin exhibit rich coordination chemistry. In fact, the Cd^{2+} site shows equally diverse coordination modes and exists in five different coordination environments [12]. However, it has been noticed that for porphyrins, cadmium(II) can coordinated only one axial ligand to form five-coordinated complexes [13]. This makes cadmium metalloporphyrins simple systems to evaluate the effect of the type of the axial ligands on the electronic and structural properties of porphyrin coordination compounds.

It is noteworthy that cadmium porphyrin derivatives exhibit several biological applications. In this context, we can mention the investigations in 2001 of Nyarko *et al.*, [14] which reported the interactions of cadmium(II), mercury(II), and lead(II) metalloporphyrins with DNA and their effects on this enzyme. Due to the fact that Cd(II), Hg(II) and Pb(II) are large divalent cations, which are known to dissociate from their metalloporphyrin complexes in the presence of DNA and ethylenediamine tetraacetic acid (EDTA). This is not the case of d transition center metals such as Mn^{3+} , Fe^{3+} and Co^{3+} , the characteristic effects of the already mentioned heavy divalent cations are expected to influence the DNA cleavage reaction. More recently, in 2012, Lee *et al.*; [15] noticed that hydrolysis of carbon dioxide is an important reaction for CO_2 collection by using accurate first-principles electronic structure calculations. These authors, predict how the catalytic hydrolysis reaction in carbonic anhydrase (CA) can be mimicked in a zinc(II) and cadmium(II) metalloporphyrins - carbon nanotube system.

Notably, morpholine is widely used as a solvent and it possesses two sites for coordination to the metal ions. In the literature, are reported the spectroscopic properties of the morpholine with divalent metallo-tetraphenyl porphyrins type $[M(TPP)]$ ($M = \text{Co(II)}$, Cu(II) , Ni(II) and Zn(II)), which elucidate the nature of ligation and the binding site of the morpholine [16].

Nevertheless, up to date no reported investigation on the effect of the coordination of morpholine axial ligand to the structural, spectroscopic, photophysical and electrochemical properties of metalloporphyrins. In this work, we report the first example of the reaction of a Cd(II) -porphyrin complex with the morpholine leading to the (morpholine)[(*meso*-tetrakis(4-chlorophenyl)porphyrinato]cadmium(II) complex with the formula $[\text{Cd}(\text{TCIPP})(\text{morph})]$ (**I**) (Scheme 1) where the morpholine axial ligand is bonded to the cadmium through the oxygen atom.

Scheme 1. Structure of $[\text{Cd}(\text{TCIPP})(\text{morph})]$ (**I**).

2. Experimental Section

2.1. Syntheses

The synthesis of the *meso*-tetrakis(*para*-chlorophenyl)porphyrin (H_2TCIPP) and the [*meso*-tetrakis(*para*-chlorophenyl)porphyrinato]cadmium(II) starting material complex $[\text{Cd}(\text{TCIPP})]$ were performed according to the methods described in the literature [17-18]. Scheme S1 gives the main steps of the preparation method.

H_2TCIPP porphyrin was obtained as purple crystals with 21% yield. ^1H NMR (300 MHz, DMSO-d_6): δ (ppm.) -2.84 (s, 2H, N-H), 7.77 (d, 8H, Hm-Ph), 8.15 (d, 8H, Ho-Ph), 8.86 (s, 8H, β -pyr). UV-vis [λ_{max} (nm) in CH_2Cl_2 , ($\epsilon \times 10^{-3}$, $\text{mol}^{-1} \cdot \text{L} \cdot \text{cm}^{-1}$)] 420(309), 517(15.8), 553(11), 589(5.6), 645(2). FTR-IR cm^{-1} : 3316 ν [(NH) porphyrin], 2960 ν [(CH) porphyrin], 967 [(δCCH) porphyrin], 780 ν (C-Cl).

[Cd(TCIPP)] was obtained as a dark green solid with 85% yield. ^1H NMR (300 MHz, DMSO- d_6) δ (ppm), 8.11 (d, 8H, $\text{H}_{\text{o-Ph}}$), 7.97 (d, 8H, $\text{H}_{\text{m-Ph}}$), 8.75 (s, 8H, β -pyr). UV/vis (CH_2Cl_2), [λ_{max} (nm) in CH_2Cl_2 , ($\epsilon \times 10^{-3}$, $\text{mol}^{-1} \times \text{L} \times \text{cm}^{-1}$): 433 (117), 568(2.3), 609(2.6). FTR-IR cm^{-1} : 2926 ν [(CH) porphyrin], 1086 [δ CCH) porphyrin], 720 ν (C-Cl).

[Cd(TCIPP)(morph)] (I) [Cd(TCIPP)] (20 mg, 0.020 mmol) and morpholine (0.5 mL, 0.125 mmol) were dissolved in 3 mL of chloroform. The solution was stirred overnight before to be filtrated. Crystals of complex (I) were obtained by slow diffusion of hexane into the chloroform solution with 80% yield (Scheme S1). Elemental analysis (%) calcd for $\text{C}_{48}\text{H}_{33}\text{Cl}_4\text{CdN}_5\text{O}$ (950.04). C, 60.68, H, 3.51, N, 7.37; found : C, 60.81, H, 3.59, N, 7.49. ^1H NMR (300 MHz, DMSO- d_6) δ (ppm), 2.64 (t, 4Hb, morph), 3.47 (t, 4Ha, morph); 5.75 (s, Hc, NH morph), 7.97 (d, 8H, $\text{H}_{\text{m-Ph}}$), 8.21 (d, 8H, $\text{H}_{\text{o-Ph}}$), 8.74 (s, 8H, β -pyr). UV/vis (CH_2Cl_2), [λ_{max} (nm) in CH_2Cl_2 , ($\epsilon \times 10^{-3}$, $\text{mol}^{-1} \text{L cm}^{-1}$): 436 (126), 575(4.4), 620(2.6). FTR-IR (cm^{-1}): 2849 ν [(CH) porphyrin], 1089 [δ CCH) porphyrin], 3293 ν (N-H) $_{\text{morph}}$, 1387 ν (C-O) $_{\text{morph}}$, 719 ν (C-Cl).

2.2 Spectroscopic and photophysical measurements:

^1H spectra were recorded using Bruker Advance 300 spectrometer. The spectra were recorded in DMSO- d_6 solutions at room temperature ($T = 298 \text{ K}$) using DMSO residual peaks ($\delta = 2.50 \text{ ppm}$) as internal references. Chemical shifts (δ) and coupling constants (J) are given in parts per million (ppm) and Hertz (Hz), respectively. Multiplicities are reported as follow: s = singlet, d = doublet, t = triplet, *m*-Ph and *o*-Ph = *meta* and *ortho* protons on the phenyl rings, and β -pyr = β -pyr protons on the pyrrole rings. Infrared spectra were recorded from 4000 to 400 cm^{-1} FT-IR Nexus (Nicolet) spectrometer. Absorbance spectra were recorded on a UV-3600 Shimadzu spectrophotometer and the concentrations of porphyrin derivatives were controlled to be *ca.* 10^{-5} M in CH_2Cl_2 . Fluorescence spectra were recorded on a Fluorolog-3 spectrofluorimeter FL3-222 with a thermostated cell compartment (25°C) using a 450 W Xenon lamp and the concentrations of porphyrin derivatives were controlled to be *ca.* 10^{-6} M in CH_2Cl_2 . The singlet oxygen production 30 was measured by the IR detector through a SPEX double grating monochromator (600 grooves/mm blazed at $1 \mu\text{m}$). All spectra were recorded using four optical faces quartz cells. Fluorescence quantum yield (ϕ_f) were determined using tetraphenyl porphyrin (H_2TPP) solution in toluene as fluorescence standard ($\phi_f = 0.11$) [19]. H_2TPP in toluene was used as standard ($\Phi_\Delta = 0.63$) [20]. The absorbance value at the excitation wavelength of the reference and the sample

solutions were set to around 0.2. The fluorescence decays were recorded using the single photon counting method. Data were collected up to 1000 counts accumulated in the maximum channel and analyzed using Time Correlated Single Photon Counting (TCSPC) software Fluofit (PicoQuant GmbH, BERLIN, Germany) based on iterative reconvolution using a Levensberg-Marquandt algorithm, enabling the obtention of multi-exponential profiles (mainly one or two exponentials in our cases).

2.3 cyclic voltammetry

Cyclic voltammetry (CV) experiments were performed with a CH-660B potentiostat (CH Instruments). The analytical experiment is conducted at room temperature under an argon atmosphere in a standard one-compartment, three-electrode electrochemical cell. Tetra-n-butylammonium perchlorate (TBAP) was used as the supporting electrolyte (0.2 m) in dichloromethane. An automatic Ohmic drop compensation procedure was systematically implemented before the CV data were recorded with electrolytic solutions containing the studied compounds at concentrations of ca. 10^{-3} M. CH Instruments vitreous carbon ($r = 3$ mm) working electrodes were polished with 1 μ m diamond paste before each recording. The Ag/AgNO₃ (TBAP 0.2 m in CH₂Cl₂) redox couple was used as the reference electrode and a platinum wire as an auxiliary electrode. For comparison with previously published data, all potentials given in the text have been converted to values relative to the saturated calomel electrode (SCE) by using the following relationship: $E(\text{SCE}) = E(\text{Ag}/\text{AgNO}_3) + 298 \text{ mV}$.

2.4 X-ray Crystallography

Single crystals of [Cd(TClPP)(morph)] (**I**) were grown at room temperature from CHCl₃-hexane mixture and carefully selected under a microscope and mounted on a Mitegen micromesh with the help of a trace of mineral oil. on a D8 VENTURE Bruker AXS diffractometer equipped with a graphite monochromatic Mo-K radiation source ($\lambda = 0.71073$ Å). The unit-cell parameters were calculated and refined from the full data and the data collection was performed with a Bruker D8 VENTURE diffractometer at 150 K. The reflections were scaled and corrected for absorption effects by using Multi-Scan method [21]. The structure was solved by direct method by using SIR-2004 program [22] and refined by full-matrix least-squares techniques on F^2 by using the SHELXL-97 program

[23]. The drawings were made with Mercury [24]. Crystal data and experimental parameters used for the intensity data collection are available free of charge from the Cambridge Crystallographic Data Centre (CCDC 1908921).

2.5 Hirshfeld surface analysis

Hirshfeld surfaces and their two-dimensional fingerprint [25-26] have been used to gaining additional insight into the intermolecular interactions in the title compound, based on results of single crystal X-ray diffraction studies. The Hirshfeld surface enveloping a molecule is defined by points where the molecule of interest and all the other molecules that surround it have the same contribution to the electronic density. For each point on that isosurface one has two distances: “ d_i ” the distance to the nearest nucleus internal to the surface, and “ d_e ” the distance from the point to the nearest nucleus external to the surface. The normalized contact distance (d_{norm}) based on both d_i and d_e , and the vdW radii of the atom [27]. The value of the d_{norm} is positive or negative when intermolecular contacts are longer or shorter than vdW separations, respectively. Because of the symmetry between d_e and d_i in the expression for d_{norm} , where two Hirshfeld surfaces touch, both will display a red spot identical in color intensity as well as size and shape. The Hirshfeld surfaces are mapped with d_i , and 2D fingerprint plots presented in this paper were generated using CrystalExplorer 3.1. Graphical plots of the molecular Hirshfeld surfaces mapped with d_{norm} (Eq. I) using a red-white-blue color scheme, where red highlights shorter contacts, white is used for contacts around the vdW separation, and blue is for longer contacts.

$$d_{\text{norm}} = \frac{d_i - r_{\text{vdW}}}{r_{\text{vdW}}} + \frac{d_e - r_{\text{vdW}}}{r_{\text{vdW}}} \quad \text{Eq. (I)}$$

3. Results and discussion

3.1 Crystal structure description

The complex (I) crystallizes in the triclinic system, space group *P*-1 with $a = 10.987(8) \text{ \AA}$, $b = 12.096(8) \text{ \AA}$, $c = 16.586(9) \text{ \AA}$, $\alpha = 88.24(2)^\circ$, $\beta = 72.54(2)^\circ$, $\gamma = 82.35(2)^\circ$, $V = 2084(2) \text{ \AA}^3$ and $Z=2$. Crystallographic data and structure refinement are reported in Table S1. The asymmetric unit of our cadmium(II) derivative consists of one [Cd(TClPP)(morph)] molecule. The atom numbering and thermal ellipsoids are shown in Figure 1. Selected bond distances and angles are given in Table 1. The Cd^{2+} ion is positioned above the porphyrin

core and coordinated to the four nitrogens of the porphyrin and axially by the oxygen atom of the morpholine axial ligand leady to a pentacoordinate Cd(II) porphyrin complex with a square pyramidal geometry.

Figure 1. ORTEP diagram of [Cd(TCIPP)morph] (I) with atomic numbering. Thermal ellipsoids shown at 50 % probability level and the hydrogen atoms are omitted for clarity.

Table 1. Selected bond lengths (Å) and angles (deg) of [Cd(TCIPP)morph] (I).

Cd–N4	2.191(5)	N1–Cd–O	99.3(2)
Cd–O	2.337(7)	N2–Cd–O	104.1(3)
		N3–Cd–O	107.2(2)
Morpholine Ligand			

O1–C62	1.490(13)	C62–O–Cd	115.3(7)
N5–C65	1.399(14)	C66–O–Cd	113.9(6)

The coordination environment around the Cd(II) center in (**I**) is presented in Figure 2 where we can see that the morpholine ligand adopts the usual chair conformation. The fact that the morpholine is coordinated to Cd(II) via the oxygen atom and not the nitrogen atom needs to be discussed. Cadmium(II) cation is known to be a soft Lewis acid and oxygen donor ligands are known to be generally hard Lewis bases while, nitrogen donor ligand are in the borderline between hard and soft base. Therefore, since the morpholine ligand is *O*-bonded to the Cd(II) central ion (soft base – soft acid), the crystallographic data confirms the Pearson “HSAB” concept [28]. The Cd—O(morph) bond length [2.337(7) Å] is considerably close to those of related non-porphyrinic cadmium–morpholine distances which are in the range [2.323–2.371 Å] (Table 2) [29]. The Cd–O bond length is close to those of reported Cd(II) porphyrin complexes with oxygen atom-coordinated axial ligands (such as H₂O and 2-dioxane) [30–32]. The average equatorial (Cd—N_p) distance is in normal range of pentacoordinate Cd(II) metalloporphyrins with a value of 2.204(5) Å. It is noteworthy that the central Cd(II) ion is, as expected, very displaced from the the N₄ plane towards the axial ligand (0.60 Å), leading to a *domed* structure of the porphyrin core of (**I**) (Figures 2 and 3). By the other hand, the distance between the cadmium atom and the mean plane made by the 24-atom core of the porphyrin (Cd–P_C) for (**I**) (0.741 Å) is similar to those of the related five-coordinated cadmium metalloporphyrin (Table 2).

^a: Cd–N_p = average equatorial distance between the cadmium and the nitrogen atoms of the porphyrin ring,

^b: Cd–O_{ax} = cadmium- oxygen axial ligand distance, ^c: Cd–P_C is the distance between the cadmium atom and the mean plane made by the 24-atom core of the porphyrin (P_C), ^d: TPP = *meso*-tetraphenylporphyrinato ^e: 18-C-6 = 1,4,7,10,13,16-hexaoxacyclooctadécane (18-crown-6), ^f: tetraphenylporphinato-bis(dioxane)cadmium(II), ^g: pip = the piperidine.

In porphyrins, the π -conjugation favor the planar structure, however, geometrical distortion can be imposed on the macrocycle by several factors: (1) packing constraints in the crystal, (2) steric crowding caused by peripheral substituents of the porphyrin ligand, (3) the effects of intramolecular interactions between atoms of the axial ligands and the porphyrinate core, (4) intermolecular interactions, typically between two porphyrins ligands, i.e., dimeric interactions, and (5) the coordination requirements of the central metal ion itself [38]. The most characteristic types of distortions of the porphyrin core are the *saddle*, the *dome*, the *ruffling* and the *wave distortion*. Thus, the *doming* distortion (*dom*) is often observed in five-coordinate complexes when the axial ligand causes a displacement of the metal center out of the mean plane, and the nitrogen atoms are also displaced toward the axial ligand, the *ruffling* distortion (*ruff*) is indicated by the values of the *meso*-carbon atoms above and below the porphyrin mean plane, the *saddle* distortion (*sad*) involves the displacement of the pyrrole rings alternately above and below the mean porphyrin macrocycle so that the pyrrole nitrogen atoms are out of the mean plane and in the *waving* distortions (*wav*), the four fragments “(β -carbon)-(α -carbon)(*meso*-carbon)-(α -carbon)-(β -carbon)” are alternatively above and below the 24-atoms of the C₂₀N₄ least squares plane (P_C plane). For the [Cd(TCIPP)(morph)] complex, the formal diagrams of the porphyrinato cores showing the displacements of each atom from the mean plane of the 24-atom porphyrin macrocycle in units of 0.01 Å is illustrated in Figure 3 where we can see that the porphyrinic core exhibits an important *doming* distortion and moderate *ruffling* and *saddle* deformations.

The supramolecular assemblies for the [Cd(TCIPP)morph] complex is depicted in Figure 4. The molecules of this complex are connected by several weak non-conventional hydrogen bonds, such as N–H $\cdots$ Cl involving the NH group of the coordinated morpholine and the Cl2 atom of the *meso*-phenylporphyrin with N5–H5A $\cdots$ Cl2 distance of 2.905(5) Å. The crystal packing is also stabilized by weak C–H $\cdots$ Cl interactions between a pyrrolic proton of one porphyrin and a chlorine atom of an adjacent porphyrin such as the C65–H65 $\cdots$ Cl3 interaction with a distance of 2.953 (7) Å (Table 3 and Figure 4). Additionally, we notice the presence of several C–H $\cdots$ π contacts, for example, the C43–H43 $\cdots$ Cg3 interaction involving the carbon C43 of a phenyl group and the centroid Cg3 of a pyrrole ring of an adjacent [Cd(TCIPP)morph] complex with a distance of 3.761(10) Å (Figure S1).The

C–H $\cdots\pi$ interaction is observed also between the carbon C65 of the morpholine ring and the centroid Cg3 with C65–H65 $\cdots$ Cg3 distance of 3.935(14) Å.

Figure 4. Schematic representation of the N–H $\cdots$ Cl and the C–H $\cdots$ Cl hydrogen bonds between the morpholine axial ligand and the chlorine atom of the adjacent *meso*-phenylporphyrin complex.

3.2 Hirshfeld Surface

For a given crystal structure, the Hirshfeld surface is unique and it suggests the possibility of obtaining additional insight into the crystal [39]. Figure 5 illustrates the Hirshfeld surfaces of the title complex, showing surfaces that have been mapped over d_{norm} . The surfaces are shown transparent for the purpose of visualizing the molecular fragment. The fingerprint plot is illustrated is given in the Figure 6 and the Hirshfeld surface, which have been mapped over a d_{norm} range of -0.6 to 2.8 Å, are shown in Figure 5. The red spots on the Hirshfeld surface indicate the presence of close contacts, whereas areas without close contacts are shown as blue spots. The crystal packing in porphyrin is mainly controlled by the close

contacts involving chlorine; $\text{Cl}\cdots\text{H}-\text{C}$, which are observed as intense red spots on the Hirshfeld surface. In the crystal, 42 % of the intermolecular contacts are associated with $\text{H}\cdots\text{H}$ contacts, 27% for the contacts between chlorine and hydrogen $\text{Cl}\cdots\text{H}$ and for the $\text{C}\cdots\text{H}$ contacts appear by the percentage contributions are 17.9%. Further, the Hirshfeld surface, shows intense red spot on the (d_e) surface near the pyrrole ring which is due to close (Porph/pyr) $\text{C}-\text{H}\cdots\text{Cl}$ and (ph) $\text{Cl}\cdots\text{H}-\text{C}$ (Porph/pyr) contacts. In addition to this, (morph) $\text{H}-\text{H}(\text{ph})$ contacts are also seen as intense red spots.

Figure 5. **(a)**: Hirshfeld surfaces mapped over d_{norm} for the title compound and **(b)**: Two-dimensional fingerprint plot with a d_{norm} of the title compound.

Figure 6. Two-dimensional fingerprint plots with a d_{norm} view of the H···H (42%), H···Cl/Cl···H (27%) and C···H/H···C (17.9%) contacts in the title compound.

3.3. ^1H NMR spectroscopy

The ^1H NMR spectrum of the free-base H_2TCIPP presents the expected profile for *meso*-tetra-substituted porphyrins molecules. For instance, the signals at $\delta = 8.86$ ppm correspond to the resonances of the β -pyrrolic protons. The phenyl protons (H_o , H_o/H_m , H_m') present chemical shift values at 8.15/7.77 ppm and the NH pyrrole protons are very shielded and appears at -2.84 ppm in the form of a low-intensity singlet. The disappearance of the resonance of the peak corresponding to the pyrrole N-H protons was observed in the ^1H NMR spectrum of the metallated porphyrin $[\text{Cd}(\text{TCIPP})]$ starting material. This spectrum of the later species is very similar to that of the free-base *meso*-porphyrin due to the diamagnetic nature of cadmium ion which is at the oxidation state (+II). For (**I**), the NMR spectrum (Figure S2) reveals also the characteristic signals of the axial morpholine ligand, where the H_a and H_b protons of the morpholine resonate at 3.47 and 2.64 ppm respectively in the form of triplet and the NH proton of the same ligand resonates as a broad singlet around 5 ppm. These values are slightly different from those of the free morpholine molecule.

3.4 IR spectroscopy

The [Cd(TCIPP)(morph)] IR spectrum has been recorded in the 4000-400 cm^{-1} domain (Figure S3) and is characteristic of a *meso*-porphyrin complex with the morpholine as axial ligand. Thus, the C-H stretching frequency of TCIPP moiety is located in the 2850 cm^{-1} spectral region. The metallated *meso*-porphyrin exhibits also absorption bands attributed to the $\delta(\text{CCH})$ vibration mode at 1089 cm^{-1} . The $\nu(\text{C-Cl})$ vibration of the *meso*-substituted porphyrin is identified as a strong absorption band at 719 cm^{-1} which is in the [800–600] cm^{-1} domain [40-41].

The IR spectrum of the title compound exhibits also a very weak absorption band at 3293 cm^{-1} corresponding to $\nu(\text{NH})$ vibration of the morpholine ligand and a band at 1387 cm^{-1} attributed to the carbonyl stretching $\nu(\text{C=O})$ of the axial ligand.

3.5 Photophysical properties

The photophysical properties such as the optical absorption, the steady state emission, the fluorescence quantum yield, the fluorescence decay and the singlet oxygen profile were studied for the porphyrin free-base H_2TCIPP , and the [Cd(TCIPP)] and [Cd(TCIPP)(morph)] complexes in dichloromethane solvent.

3.5.1 UV-vis spectroscopy

Metalloporphyrins display usually two types of absorption bands, i.e., intensive B band (known as the Soret band) locating at about 400 nm corresponds to $\text{S}_0 \rightarrow \text{S}_2$ transition with the value of ϵ (namely, molar absorption coefficient) being about $10^5 \cdot \text{M}^{-1} \cdot \text{cm}^{-1}$ and four weak Q bands residing at about 500– 650 nm corresponds to $\text{S}_0 \rightarrow \text{S}_1$ transition with the ϵ values being about 10^3 – $10^4 \text{ M}^{-1} \cdot \text{cm}^{-1}$. The normalized absorption spectra of the free base porphyrin H_2TCIPP , [Cd(TCIPP)] and [Cd(TCIPP)(morph)] complexes are presented in Figure 7. The value of the λ_{max} of the Soret absorption band of the free base H_2TCIPP appears at 420 nm while, the four Q bands are found at 517, 553, 589, and 645 nm. The λ_{max} value of the Soret band is 433 nm for [Cd(TCIPP)] which is red-shifted by 13 nm while the number of Q-band is reduced to two which are located at 568 and 609 nm (Table S2). The difference of the Q-band number between [Cd(TCIPP)] and the free base H_2TCIPP is attributed to the increase of the molecular symmetry originated from the metalation of the porphyrinic macrocycle center of the free base H_2TCIPP . Whereas for (I) the λ_{max} values of

the Soret and Q bands are 436 nm for the first band and 575, and 620 nm for the latter band, which are slightly red-shifted compared with those of [Cd(TCIPP)] indicating the complexation of the morpholine axial ligand. This is also the case for others related five-coordinated metalloporphyrins [$M^{II}(\text{TPP})(\text{Morph})$] ($M = \text{Co}, \text{Cu}, \text{Ni}$ and Zn) (Table S2). It is noteworthy that the higher redshift of the absorption bands is related mainly to the important distortion of the porphyrin core [10-11]. The higher atomic radius of Cd(II) metal ion compared to the other metals ($M = \text{Zn}, \text{Cu}, \text{Ni}, \text{Co}$) (Table S2) implies that Cd(II) is too large to fit into the central hole of the TCIPP which generates significant the deformations of the TCIPP core and the complexation of the morpholine *O*-donor axial ligand tends to increase the doming distortion by pulling out the Cd(II) metal ion from of the porphyrinato plane. The optical band gap energy (E_g) refers to the energy difference between the HOMO and the LUMO orbitales of the porphyrin species can be calculated from the UV-visible spectrum using the Tauc plot method [42]. The E_g values in CH_2Cl_2 solution are 1.960 and 1.903 eV for [Cd(TCIPP)] and [Cd(TCIPP)(morph)] respectively, indicating that the gap energy of the metallized species are higher than that obtained for H_2TCIPP free base (1.820 eV) (Table S2) suggesting that the Cd-*meso*-porphyrin display interesting organic semiconducting properties [43].

Figure 7. UV-visible absorption spectra in CH_2Cl_2 ($c = 10^{-5} \text{ M}$) of H_2TCIPP , $[\text{Cd}^{II}(\text{TCIPP})]$, and $[\text{Cd}^{II}(\text{TCIPP})(\text{morph})]$ (I).

3.5.2 Steady-State fluorescence and Singlet oxygen

The steady-state fluorescence of porphyrins was performed in order to study their electronic properties in excited state. The fluorescence emission spectra of the free base porphyrin

(H₂TCIPP), [Cd(TCIPP)] and [Cd(TCIPP)(morph)] coordination compounds at room temperature were recorded in CH₂Cl₂ ($c = 10^{-6}$ M) under the excitation wavelength of 433 nm (Figure-8a). Table 5 summarizes the maxima of the fluorescence of the Q(0,0) and Q(0,1) bands, the fluorescence quantum yields (Φ_f) and the fluorescence lifetimes (τ_f) of our derivatives (**I**) as well as a selected species. The emission spectrum of the free base porphyrin H₂TCIPP in CH₂Cl₂ exhibits two well-defined emission bands near 605 nm (Q(0,0)) and 657 nm (Q(0,1)) displays two emission Q bands at 650 and 717 nm (Q(0,0) and Q(0,1), respectively), the emission spectrum of [Cd(TCIPP)] shows a 31 nm (from 650 to 619 nm) and a 67 nm (from 717 to 650 nm) blue shifts of the Q(0,0) and Q(0,1) bands, respectively, accompanied by a decline of fluorescence intensity, Φ_f and τ_f (**Fig. 8a**). Thus, after the insertion of cadmium ions into the porphyrin cavity, the emission band became blue-shifted and less intense compared to those of free-base porphyrin (**Table 6**), indicating that the structure of the originally flat porphyrin (free base porphyrin H₂TCIPP) is distorted in out-of-plane [Cd(TCIPP)] causing a dome distortion in the structure, consequently the Φ_f decrease. The decrease of the fluorescence quantum yield can be also explained by the high molar mass of Cd(II) which leads to a quenching effect, resulting in the very low Φ_f values. Which may be due to other non-radiative energy dissipation processes such as enhanced internal conversion, intersystem crossing [44-45]. The emission spectrum of complex (**I**) is quite similar to that of [Cd(TCIPP)] and shows that the coordination of the morpholine *O*-donor axial ligand to Cd(II) metal ion have a minor effect. This result suggests that the out-of-plane distortion of porphyrin rings in [Cd(TCIPP)] and [Cd(TCIPP)(morph)] complex are relatively similar.

The Fluorescence lifetimes (τ_f) were measured by time-correlated single photon counting technique. The representative fluorescence decays for the free base H₂TCIPP, [Cd(TCIPP)] and [Cd(TCIPP)(morph)] are shown in Figure. S4. The τ_f values of the free base H₂TCIPP (~ 8.9 ns) is as expected much higher than those of [Cd(TCIPP)] and [Cd(TCIPP)(morph)] which are ~1.6 and ~1.5 ns respectively (Table 6). We notice that the τ_f of the cadmium porphyrins is not influenced by the axial ligand. Whereas the lifetimes of the fluorescences decrease consequence of the macrocycle distortion [46] and mainly to the large Cd atom.

Figure 8. **(a)** : Fluorescence emission spectra and **(b)** : Singlet oxygen production spectra performed at $\lambda_{\text{ex}} = 433$ nm of H_2TCIPP , $[\text{Cd}^{\text{II}}(\text{TCIPP})]$ and $[\text{Cd}^{\text{II}}(\text{TCIPP})(\text{morph})]$, in CH_2Cl_2 ($c \sim 10^{-6}$ M) at room temperature.

^a: Fluorescence spectra of porphyrins were obtained as a function of $\lambda_{\text{ex}} = 433$ nm.

^b: Fluorescence quantum yield, ^c: Fluorescence lifetime (ns), ^d: Singlet oxygen production quantum yield. ^e: in toluene solvent, ^f: in ethanol solvent, ^g: in THF solvent.

Singlet oxygen production was detected in the infrared region, following excitation of the porphyrin at 433 nm. Figure 8b illustrates the singlet oxygen production spectra of the our synthetic compounds with the maximum emission at 1270 nm. As seen in Table 5, the $[\text{Cd}^{\text{II}}(\text{TCIPP})(\text{morph})]$ presents the highest singlet oxygen quantum yield ($\Phi_{\Delta} = 0.53$) compared to $[\text{Cd}^{\text{II}}(\text{TCIPP})]$ ($\Phi_{\Delta} = 0.41$) and H_2TCIPP ($\Phi_{\Delta} = 0.49$). The singlet oxygen quantum yield depends generally on the intersystem crossing rate. Thus, the increase of Φ_{Δ} for the $[\text{Cd}^{\text{II}}(\text{TCIPP})(\text{morph})]$ can be attributed to the structure distortion caused by the insertion of the cadmium heavy metal as well as the coordination of morpholine axial ligand. These factors are thought to promote the intersystem crossing rate through the enhanced spin-orbit coupling, consequently, increase the triplet quantum yield [50-51].

3.6 Cyclic Voltammetry

The electrochemical behavior of the free base H₂TCIPP, the starting material [Cd(TCIPP)] and the [Cd(TCIPP)(morph)] complex (**I**) were studied by cyclic voltammetry (CV) with the tetra-n-butylammonium hexafluorophosphate (TBAPF₆) as the supporting electrolyte (0.2 M) in the non-coordinating solvent CH₂Cl₂ under an argon atmosphere. In Figure 9 is illustrated the voltammogram of (**I**) while in Table 6 is summarized the CV data of the free base, the starting material, complex (**I**) and a selection of some *meso*-porphyrins and zinc(II) metalloporphyrins. cadmium(II) as well as zinc(II) cations for which the correspondent metal belong to the same 12 group exhibit the 4d¹⁰ and 3d¹⁰ ground state electronic configurations respectively. Therefore, these cations are diamagnetic and only the oxidation and reduction waves of the porphyrin ring are observed in the voltammograms. Indeed, the CV of the H₂TCIPP, the [Cd(TCIPP)] and the [Cd(TCIPP)(morph)] present each one a two one-electron reduction waves and three one-electron oxidation waves (Table 6). We notice that the values of the half potentials ($E_{1/2}$) for the metallated porphyrin are shifted toward more negative values compared to the H₂TCLPP species. This is also the case of zinc(II) metalloporphyrins. Unfortunately, up to date, there are no reported CV data of Cd(II) metalloporphyrins, nevertheless, the $E_{1/2}$ values of complex (**I**) are quite smaller than those of the related zinc(II) pent-coordinated [Zn(TPP)(Him)] [52] and [Zn(TPBP)(4,4'-mda)] [53] complexes.

The cadmium-porphyrin HOMO-LUMO gap can be expressed as the potential difference of the first oxidation and the first reduction. is given by the empirical rule of Fuhrhop *et al.*, [54]. This energy gap is known as the electrochemical gap (E_{g-el}). The electrochemical Gap values are 2.20, 2.00 and 1.94 eV pour our three species H₂TCIPP, [Cd(TCIPP)] and [Cd(TCIPP)(morph)] respectively are as expected higher than those of the optical gap (see UV-visible section). We notice that the tetra-coordinated and the penta-coordinated zinc(II) complexes reported in Table 6 present E_{g-el} values close to those of our [Cd(TCIPP)] and [Cd(TCIPP)(morph)].

Figure 9. Cyclic voltammogram of $[\text{Cd}(\text{TCIPP})(\text{morph})]$ (**I**). The solvent is CH_2Cl_2 , and the concentration is ca. 10^{-3} M in 0.2 M (TBAP), 100 mVs^{-1} , vitreous carbon working electrode ($\varnothing = 3 \text{ mm}$).

4. Conclusion

In summary, we have synthesized and characterized the five-coordinate cadmium(II) *meso*-tetrachlorophenylporphyrin complex with the oxygen coordinated morpholine to the central metal. The structure of $[\text{Cd}(\text{TCIPP})\text{morph}]$ (**I**) complex was determined by single-crystal X-ray crystallographic analysis. The molecules of this complex are connected by hydrogen bonds type $\text{N-H}\cdots\text{Cl}$, $\text{C-H}\cdots\text{Cl}$, and $\text{C-H}\cdots\pi$. By the other hand, based on Hirshfeld topology analyses all possible intermolecular interactions occurring in the crystal structure have been quantified. The displacement of the $\text{Cd}(\text{II})$ metal atom out of the porphyrinato mean plane is $0.74 \text{ \AA}$. This high value induces a significant porphyrinato core *doming*, moderate *ruffling* and *saddle* distortion. Absorption spectra reveal that the insertion of $\text{Cd}(\text{II})$ metal ion into TCIPP and the addition of the morpholine axial ligand are accompanied by a redshift of the Soret and Q bands of the $[\text{Cd}(\text{TCIPP})]$ starting material and the $[\text{Cd}(\text{TCIPP})(\text{morph})]$ complex. While the Q bands of fluorescence emission spectra are blue-shifted with a decrease of the fluorescence intensity, quantum yield (ϕ_f) and lifetime (τ_f). The important singlet oxygen quantum yield (Φ_Δ) makes this complex a good candidate to develop antibacterial and antiviral treatments. The cyclic voltammetry investigation on the H_2TCIPP , the

starting material [Cd(TCIPP)] and complex (**I**) are also reported and the electrochemical gap values of these porphyrinic species were determined from the CV voltammogram which are slightly higher than those of the optical gap.

Supporting information

CCDC 1908921 contain the supplementary crystallographic data of complex **(I)**. These data can be obtained free of charge from the Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

The five-coordinate cadmium(II) *meso*-tetrachlorophenylporphyrin complex, containing morpholine *O*-donor as axial ligand was prepared. Their Structural and Photophysical properties have been studied.
