ABSTRACT: In aqueous solution, cyclodextrins (CDs) are able to bind strongly either hydrophobic species or also hydrophilic molecules such as octahedral hexametallic cluster. Systematic investigation of the reactivity between native CDs (α - or β -CD) and water-soluble rhenium clusters $[\text{Re}_6\text{Q}_8(\text{CN})_6]^{4-}$ with Q = S, Se, and Te have been carried out leading to six new crystal structures revealing different types of supramolecular arrangements. Encapsulation of $[\text{Re}_6\text{Q}_8(\text{CN})_6]^{4-}$ (Q = S, Se or Te) within two β -CDs is observed regardless of the cluster size. Interestingly, different assembling scenarios are pointed out depending on the host-guest matching featured by no, partial or deep inclusion complexes that involved either primary or secondary rim of the CD tori. In the specific case of α -CD, only the smaller cluster $[\text{Re}_6\text{S}_8(\text{CN})_6]^{4-}$ is able to form inclusion complex with the tori host. Solution investigations, using a set of complementary techniques including isothermal titration calorimetry (ITC), multinuclear NMR methods, cyclic voltammetry, and electrospray ionization mass spectrometry (ESI-MS), corroborate nicely conclusions of the solid state studies. It appears clearly that size-matching supported by solvent effects play key roles in the stability of the host-guest complexes. At last, circular dichroism studies underline that the chirality induction from cyclodextrins to the rhenium cluster depends strongly on the strength of host-guest interactions.

INTRODUCTION

Cyclodextrins (CDs) represent an attractive class of water-soluble macrocyclic hosts able to trap or encapsulate adapted guest molecules,¹ that makes them relevant for applications in various domains of industry such as chemical, cosmetics, food or medicine.²⁻⁴ Native CDs are constituted of six (α -CD), seven (β -CD) or eight (γ -CD) glucopyranoside units defining semi-flexible toroidal host. Due to the hydrophobic character of their cavity, CDs are known to form robust inclusion complexes with hydrophobic molecules. During decades, the hydrophobic effect and the steric repulsion have been considered as the main contributors to the host-guest association ability of CDs. Nevertheless, recent reports revealed that CDs can also bind hydrophilic molecules, such as polyoxometalates,⁵⁻⁸ metal atoms clusters^{7,9} or dodecaborates.¹⁰⁻¹² Interestingly, stability of resulting host-guest complexes can approach or even outperform those of conventional adducts built from hydrophobic guests. Such unexpected associations can be understood from solvation properties of the ionic guests described as chaotrope or kosmotrope species according to the Hofmeister classifica-

tion.^{10,13-16} Therefore, thermodynamic fingerprint related to supramolecular complexation or adsorption process on surface reveals the chaotropic nature of these polynuclear ions that involve the release of water molecules in the bulk with the concomitant strengthening of hydrogen bonds. Actually, some ionic species has been even identified as “superchaotrope” leading to highly stable supramolecular aggregates with organic matter such as macrocyclic hosts,^{15,17,18} lipid surfaces,¹⁹ membranes,²⁰ or proteins.²¹⁻²⁴ The control of such self-assembly process recently emerged as an innovative route to hierarchical hybrid supramolecular assemblies.¹³ Octahedral rhenium cluster complexes due to their antitumoral, anti-bacterial, photoluminescent, redox and X-ray contrast properties are appealing inorganic species for applications in biology and medicine.²⁵⁻³⁵ Their encapsulation within biocompatible drug carrier, such as cyclodextrins, represents a promising way to develop biological applications. In context, we demonstrated that clusters $[\text{Re}_6\text{Q}_8(\text{CN})_6]^{4-}$ (with Q = S, Se and Te, see Figure 1a-c) interact with γ -CD, forming strong host-guest complexes built on cluster embedded within two tori hosts.⁹

Figure 1: Structural representation of the molecular components used for designing host-guest entities. The inorganic guests are octahedral rhenium clusters $[\text{Re}_6\text{Q}_8(\text{CN})_6]^{4-}$ with $\text{Q} = \text{S}$ (a), Se (b) and Te (c) built from a $\{\text{Re}_6\}$ core formed by six Re^{III} atoms linked through metal-metal bonds. The octahedral $\{\text{Re}_6\}$ core is face capped by eight $\mu_3\text{-Q}$ ligands. The coordination sphere of Re centers is completed by cyano ligands in apical positions. The supramolecular hosts are α - (d), β - (e) and γ -cyclodextrin (f) resulting from the condensation of 6, 7 and 8 glucopyranose units, respectively. Colour code: green = Re , yellow = S , orange = Se , brown = Te , grey = C , blue = N , red = O .

Interestingly, the host-guest stability of such inclusion complexes appears strongly influenced by the nature of the inner chalcogenide ligands (Q) and varies significantly in the following order $\text{S} < \text{Se} < \text{Te}$. Surprisingly, this trend of binding hierarchy corresponds to the reverse of chaotropic character of the cluster, meaning that host/guest dispersion energies have also a decisive contribution on the stability of $[\text{Re}_6\text{Q}_8(\text{CN})_6]^{4-}/\gamma\text{-CD}$ inclusion complexes. Furthermore such behaviour could highlight that the main contributors arising from the solvent could be even more intricate than those simply depicted as chaotrope vs kosmotrope. Based on these conclusions, we hypothesized the possibility to recognize selectively these guest entities with appropriate macrocyclic hosts designed as CDs (α -, β - or γ -CD).

In this paper, we investigate systematically the effect of cyclodextrin cavity size (Figure 1) on the supramolecular complexation of anionic rhenium clusters $[\text{Re}_6\text{Q}_8(\text{CN})_6]^{4-}$ in aqueous solution. Six supramolecular assemblies have been successfully isolated as single crystals by slow evaporation or through solvent vapour diffusion. Structural models of β -CD based compounds $\text{Re}_6\text{S}_8@ \beta\text{-CD}$, $\text{Re}_6\text{Se}_8@ \beta\text{-CD}$ and $\text{Re}_6\text{Te}_8@ \beta\text{-CD}$ reveal the inclusion of the $[\text{Re}_6\text{Q}_8(\text{CN})_6]^{4-}$ clusters within two β -CDs. A distinct scenario is observed with α -CD since only the smaller cluster exhibits a host-guest arrangement, $\text{Re}_6\text{S}_8@ \alpha\text{-CD}$. The two larger clusters interact mainly with the outer surface of α -CD as observed in the structure of $\text{Re}_6\text{Se}_8(\alpha\text{-CD})$ and $\text{Re}_6\text{Te}_8(\alpha\text{-CD})$. Solution investigations, using a set of complementary techniques (isothermal titration calorimetry, cyclic voltammetry, multinuclear NMR, ESI-MS and circular dichroism) bring valuable insights allowing better understanding about the structure-stability relationship.

These results complement nicely our previous report demonstrating clearly the ability of CDs to recognize selectively rhenium clusters through a size-exclusion mechanism.

EXPERIMENTAL SECTION

Synthesis: The compounds described herein were synthesized from aqueous mixtures of α -cyclodextrin (TCI, 98%) or β -cyclodextrin (TCI, 98%) and $\text{K}_4[\text{Re}_6\text{Q}_8(\text{CN})_6]$ with $\text{Q} = \text{S}$, Se , or Te . The starting chemical reactants were commercially available and were used without any further purification except $\text{K}_4[\text{Re}_6\text{Q}_8(\text{CN})_6]$ compounds which were synthesized as described in literature.^{36,37}

$\text{K}_4[\text{Re}_6\text{S}_8(\text{CN})_6] \cdot (\alpha\text{-CD})_2 \cdot 15\text{H}_2\text{O}$ noted $\text{Re}_6\text{S}_8@ \alpha\text{-CD}$: $\text{K}_4[\text{Re}_6\text{S}_8(\text{CN})_6]$ (0.15 g; 0.089 mmol) and α -CD (0.259 g; 0.266 mmol) were dissolved in 2 mL of deionized (DI) water. The slow evaporation of the resulting solution gave small orange crystals of $\text{Re}_6\text{S}_8@ \alpha\text{-CD}$. Yield 0.26 g (75%) of pure crystalline product. EDS shows $\text{Re} : \text{S} : \text{K}$ ratios = 6.0 : 7.8 : 3.9. Anal. Calcd for $\text{C}_{78}\text{H}_{150}\text{K}_4\text{N}_6\text{O}_{75}\text{Re}_6\text{S}_8$: C, 23.97; H, 3.87; N, 2.15. Found: C, 23.9; H, 4.0; N, 2.2. Thermogravimetric analysis revealed a weight loss of about 6.8% from 50 to 200 °C (the calculated weight loss of 15 H_2O is 6.9%).

$\text{K}_4[\text{Re}_6\text{Se}_8(\text{CN})_6] \cdot (\alpha\text{-CD}) \cdot 6\text{H}_2\text{O}$ noted $\text{Re}_6\text{Se}_8(\alpha\text{-CD})$: $\text{K}_4[\text{Re}_6\text{Se}_8(\text{CN})_6]$ (0.15 g, 0.072 mmol) and (0.211 g, 0.217 mmol) of α -CD were dissolved in 2 mL of DI water. Crystals of $\text{Re}_6\text{Se}_8(\alpha\text{-CD})$ were obtained by slow ethanol vapour diffusion into water solution (10 mL vessel containing 2 mL of water solution was placed into a 250 mL vessel with a tight-fitting lid containing 50 mL of ethanol) after two days and were collected, washed with water/ethanol mixture and dried on air. Yield 0.148 g (65%) of pure crystalline product. EDS shows $\text{Re} : \text{Se} : \text{K}$ ratios = 6.0 : 8.2 : 4.0. Anal. Calcd for $\text{C}_{42}\text{H}_{72}\text{K}_4\text{N}_6\text{O}_{36}\text{Re}_6\text{Se}_8$: C, 15.98; H, 2.30; N, 2.66. Found: C, 16.1; H, 2.2; N, 2.7. Thermogravimetric analysis revealed a weight loss of about 3.6% from 50 to 200 °C (the calculated weight loss of 6 H_2O is 3.4%).

$\text{K}_4[\text{Re}_6\text{Te}_8(\text{CN})_6] \cdot 2(\alpha\text{-CD}) \cdot 20\text{H}_2\text{O}$ noted $\text{Re}_6\text{Te}_8(\alpha\text{-CD})$: the same procedure was applied as for $\text{Re}_6\text{Se}_8(\alpha\text{-CD})$ but using 0.15 g (0.061 mmol) of $\text{K}_4[\text{Re}_6\text{Te}_8(\text{CN})_6]$ and 0.177 g (0.182 mmol) of α -CD. Yield 0.209 g (72%) of pure crystalline product. EDS shows $\text{Re} : \text{Te} : \text{K}$ ratios = 6.0 : 8.0 : 4.1. Anal. Calcd for $\text{C}_{78}\text{H}_{160}\text{K}_4\text{N}_6\text{O}_{80}\text{Re}_6\text{Te}_8$: C, 19.60; H, 3.38; N, 1.76. Found: C, 19.4; H, 3.5; N, 1.8. Thermogravimetric analysis revealed a weight loss of about 7.5% from 50 to 200 °C (the calculated weight loss of 20 H_2O is 7.6%).

$\text{K}_4[\text{Re}_6\text{Q}_8(\text{CN})_6] \cdot (\beta\text{-CD})_2 \cdot 2(\beta\text{-CD}) \cdot n\text{H}_2\text{O}$ with $\text{Q} = \text{S}$ ($n = 25$), Se ($n = 21$), or Te ($n = 25$) noted $\text{Re}_6\text{S}_8@ \beta\text{-CD}$, $\text{Re}_6\text{Se}_8@ \beta\text{-CD}$ and $\text{Re}_6\text{Te}_8@ \beta\text{-CD}$: the same procedure was applied as for $\text{Re}_6\text{Se}_8(\alpha\text{-CD})$ but using 0.074, 0.091 or 0.109 g (0.044 mmol) of $\text{K}_4[\text{Re}_6\text{Q}_8(\text{CN})_6]$ for $\text{Q} = \text{S}$, Se or Te , respectively, and 0.15 g (0.132 mmol) of β -CD.

$\text{Re}_6\text{S}_8@ \beta\text{-CD}$: Yield 0.171 g (58%) of pure crystalline product. EDS shows $\text{Re} : \text{S} : \text{K}$ ratios = 6.0 : 8.2 : 4.1. Anal. Calcd for $\text{C}_{174}\text{H}_{330}\text{K}_4\text{N}_6\text{O}_{165}\text{Re}_6\text{S}_8$: C, 31.27; H, 4.98; N, 1.26. Found: C, 31.4; H, 5.0; N, 1.3. Thermogravimetric analysis revealed a weight loss of about 6.9% from 50 to 200 °C (the calculated weight loss of 25 H_2O is 6.8%).

Re₆Se₈@ β -CD: Yield 0.169 g (55%) of pure crystalline product. EDS shows Re : Se : K ratios = 6.0 : 7.9 : 3.8. Anal. Calcd for C₁₇₄H₃₂₂K₄N₆O₁₆₁Re₆Se₈: C, 29.88; H, 4.64; N, 1.20. Found: C, 30.0; H, 4.5; N, 1.1. Thermogravimetric analysis revealed a weight loss of about 5.4% from 50 to 200 °C (the calculated weight loss of 21 H₂O is 5.4%).

Re₆Te₈@ β -CD: Yield 0.178 g (54%) of pure crystalline product. EDS shows Re : Te : K ratios = 6.0 : 8.1 : 3.9. Anal. Calcd for C₁₇₄H₃₃₀K₄N₆O₁₆₅Re₆Te₈: C, 27.99; H, 4.46; N, 1.13. Found: C, 28.0; H, 4.5; N, 1.1. Thermogravimetric analysis revealed a weight loss of about 6.0% from 50 to 200 °C (the calculated weight loss of 25 H₂O is 6.0%).

Single Crystal X-ray Diffraction: Crystals of compounds **Re₆S₈@ α -CD**, **Re₆Se₈(α -CD)**, **Re₆Te₈(α -CD)**, **Re₆S₈@ β -CD**, **Re₆Se₈@ β -CD** and **Re₆Te₈@ β -CD**, were selected under polarizing optical microscope and glued in paratone oil to prevent any loss of crystallization water. X-ray intensity data were collected at low temperature (T = 200(2) K) on a Bruker X8 APEX2 with a CCD area detector using Mo K α radiation (λ = 0.71073 Å). Data reduction was accomplished using SAINT V7.53a. The substantial redundancy in data allowed a semi-empirical absorption correction (SADABS V2.10) to be applied, on the basis of multiple measurements of equivalent reflections. Using Olex2,³⁸ the structure was solved with the ShelXT³⁹ structure solution program using Intrinsic Phasing and refined with the ShelXL⁴⁰ refinement package using Least Squares minimization. The remaining non-hydrogen atoms were located from Fourier differences and were refined with anisotropic thermal parameters. Positions of the hydrogen atoms belonging to the cyclodextrins were calculated. In the compounds exhibiting host-guest inclusion complexes **Re₆S₈@ α -CD**, **Re₆S₈@ β -CD**, **Re₆Se₈@ β -CD** and **Re₆Te₈@ β -CD**, the cluster is disordered over two positions. Crystallographic data for single-crystal X-ray diffraction studies are summarized in Table S1 and Table S2 for compounds based on α -CD and β -CD, respectively. CIF files can be obtained free of charge from the Cambridge Crystallographic Data Centre via <https://www.ccdc.cam.ac.uk>. Deposit number: 1905524 for **Re₆S₈@ α -CD**, 1905525 for **Re₆Se₈(α -CD)**, 1905526 for **Re₆Te₈(α -CD)**, 1905527 for **Re₆S₈@ β -CD**, 1905528 for **Re₆Se₈@ β -CD** and 1905529 for **Re₆Te₈@ β -CD**.

NMR studies. All NMR spectra were measured in D₂O at 27 °C. ⁷⁷Se and ¹²⁵Te NMR spectra were measured on a Bruker Avance 400 spectrometer at Larmor frequencies of 76.3 and 126.3 MHz, using H₂SeO₃ in alkaline solution (1272.6 ppm) and aqueous H₆TeO₆ (713 ppm) as external secondary references, respectively. ¹H NMR spectra were recorded on a 300 MHz spectrometer. Chemical shifts were referenced to tetramethylsilane (TMS).

ITC. Formation constants and inclusion enthalpies were simultaneously determined for each system by the use of an isothermal calorimeter (ITC200, MicroCal Inc., USA), at three temperatures (283, 298 and 313 K). See Supporting Information for further details.

Electrochemistry. Cyclic voltammetric (CV) experiments were carried out with a Metrohm Autolab PGSTAT230 driven by a computer using NOVA software. Measurements were performed at room temperature in a conventional single compartment cell. A glassy carbon (GC) electrode with a diameter of 3 mm was used as the working electrode. The auxiliary electrode was a Pt

plate and potentials are quoted against a saturated calomel electrode (SCE). The solutions were deaerated thoroughly for at least 10 minutes with pure argon. The solution was prepared by dissolving 0.01 mmol of metal cluster in 20 mL of aqueous solution of 2.5 mM HClO₄. Then different amounts of cyclodextrin have been added under stirring.

Electrospray Ionization Mass Spectrometry (ESI-MS). Electrospray ionization mass spectra were collected using a Q-TOF instrument supplied by WATERS. Samples were dissolved in water at a concentration of 1 g/L (based on metal cluster) and were introduced into the spectrometer via an ACQUITY UPLC WATERS system whilst a Leucine Enkephalin solution was co-injected via a micro pump as internal standard.

Circular dichroism. Circular dichroism spectra were recorded in the range 200-350 nm with a home-made spectropolarimeter. The basic principle relies on direct measurements of the CD signals corresponding to the differential absorbance between left- and right-circularly polarized light: $CD = A_L - A_R$.

To this end, fast modulation of the light was achieved by a photo-elastic modulator coupled with a phase sensitive detection. CD investigations have been carried out on solutions containing large excess of CDs (100 mM for α - and γ -CD, and 14 mM for β -CD). For these measurements, the sample absorbance was adjusted to about 1 (for 1 mm optical path) at the absorption maximum. The cluster concentration was fixed at 0.3, 0.18 and 0.06 mM for S-, Se- and Te- derivatives, respectively. The CD signals can be also correlated to the sample ellipticity θ expressed in degrees, as follow: $\theta \sim 32.9 \times (A_L - A_R)$.

Infrared spectroscopy. Fourier Transform Infrared (FT-IR) spectra were recorded on a 6700 FT-IR Nicolet spectrophotometer, using diamond ATR technique. The spectra were recorded on non-diluted compounds in the range 400-4000 cm⁻¹. The IR spectra are provided in Supporting Information (see Figs. S1-2).

Energy-Dispersive X-ray Spectroscopy. EDS measurements were performed using a SEM-FEG (Scanning Electron Microscope enhanced by a Field Emission Gun) equipment (JSM 7001-F, Jeol). The measurements were acquired with a SDD XMax 50 mm² detector and the Aztec (Oxford) system working at 15 kV and 10 mm distance. The quantification is realized with the standard library provided by the constructor using L α lines.

RESULTS and DISCUSSION

Synthesis of supramolecular hybrid compounds

The supramolecular hybrid compounds constructed from octahedral rhenium clusters [Re₆Q₈(CN)₆]⁴⁺ (Q = S, Se, Te) and cyclodextrins have been systematically isolated from aqueous mixtures containing water-soluble rhenium clusters K₄[Re₆Q₈(CN)₆] with three equivalents of CD. Crystals of **Re₆S₈@ α -CD** were obtained by slow evaporation, while single crystals of **Re₆Se₈(α -CD)** and **Re₆Te₈(α -CD)** were obtained by ethanol vapour diffusion. To avoid crystallization of β -CD which exhibits low solubility in water, the isolation of **Re₆S₈@ β -CD**, **Re₆Se₈@ β -CD** and **Re₆Te₈@ β -CD** have been performed also by ethanol vapour diffusion. The composition of all compounds has been established by different complementary techniques (elemental

analysis, EDS, IR and TGA) in accordance with the single-crystal X-ray diffraction analysis.

Structure description of supramolecular hybrid compounds

Re₆S₈@ α -CD crystallizes in the non-centrosymmetric space group *C*₂ and its structure contains two crystallographically independent rhenium clusters which are encapsulated into two α -CDs (Figure 2a). In this host-guest assembly, the secondary face of α -CD interacts with the inorganic guest, which has been previously observed between γ -CD and the clusters [Re₆Q₈(CN)₆]⁴⁻ with Q = Se and Te.⁹ The equatorial plan of octahedral clusters [Re₆S₈(CN)₆]⁴⁻ lined by four cyano groups is parallel to α -CDs, and the two other cyano groups point to the centre of both symmetric host cavities. This host-guest organization induces supramolecular stabilization through numerous hydrogen bonds. The four equatorial cyano groups contribute to the supramolecular stabilization through hydrogen bonding with their closest hydroxyl groups of the secondary face, giving an average N...H-O distance of 3.04 Å. In addition, each inner ligand, herein sulphur, interacts weakly with the hydrogen atoms commonly named H-3 (see Figure 6 for H labelling) with distances range C-H...S = 2.6-2.9 Å.

Figure 2: Mixed representations of the solid state structure of compound Re₆S₈@ α -CD containing the [Re₆S₈(CN)₆]⁴⁻ anion and α -CD. a) Supramolecular discrete host-guest arrangement showing two secondary faces embedding the rhenium-sulphide cluster; b) view of the unit cell highlighting the packing of the inclusion complexes along the *b* axis. Counter cations (K⁺), hydrogen atoms of α -CD and free water molecules were omitted for clarity.

Interestingly, within this supramolecular adduct, the shortest distance between two hydroxyls of distinct CD is around 5.8 Å, indicating the absence of interactions between the CDs. This configuration strongly differs from the host-guest adducts involving γ -CDs and [Re₆Q₈(CN)₆]⁴⁻ with Q = Se and Te, where numerous H-bonds were observed between the two γ -CDs, favouring the supramolecular stabilization.⁹ In the crystal packing of **Re₆S₈@ α -CD**, two host-guest entities {[Re₆S₈(CN)₆]₂@(α -CD)₂}⁴⁻ are stacked together through their primary faces along the *b* axis giving the typical bamboo-like arrangement (Figure 2b). The 3D cohesion is ensured by the counter cations, potassium ions, which are located between the tubules.

Re₆Se₈(α -CD) crystallizes in the space group *P*₂₁ and its structure contains one crystallographically independent rhenium cluster and one α -CD. The crystal structure of **Re₆Se₈(α -CD)** differs from **Re₆S₈@ α -CD** and results rather from a co-crystallization process between CD and cluster without formation of host-guest complexes. Then, [Re₆Se₈(CN)₆]⁴⁻ clusters are almost located in the centre of

rectangle defined by four α -CDs oriented in the (*bc*) plane (Figure 3a and 3b). The *C*₃ axis of the octahedral metal cluster is parallel with the central α -CD axis. In such arrangement, clusters interact weakly with the outer wall of α -CDs. Besides, three cyano groups participate to the network stabilization through three hydrogen bonds with closest hydroxyl of the primary face, giving N...O distances in the 2.75-3.04 Å range. These weak interactions between the cluster units and α -CDs promote the formation of 2D extended hybrid organic-inorganic layers. The 3D cohesion is then ensured by the cations, potassium ions found between the 2D anionic planes.

Figure 3: View of the structure of **Re₆Se₈(α -CD)** and **Re₆Te₈(α -CD)**. Each cluster interacts with the outer surface of the α -CD. This arrangement involves the formation of supramolecular 2D-sheet in the *bc* plane for **Re₆Se₈(α -CD)** (a) and in the *ab* plane for **Re₆Te₈(α -CD)** (c). b) View of the unit cell of **Re₆Se₈(α -CD)** highlighting the stacking of supramolecular sheet along the perpendicular direction to the *bc* plane. d) View of the unit cell of **Re₆Te₈(α -CD)** showing the supramolecular organization resulting from the assembly of two types of layers perpendicular to the *c* direction: a hybrid layer containing two 2D-sheets and a layer of free α -CDs (CD in purple). Counter cations (K⁺), hydrogen atoms of α -CD and free water molecules were omitted for clarity.

Re₆Te₈(α -CD) crystallizes in the space group *P*₂₁₂₁₂₁ and its structure contains one crystallographically independent rhenium cluster and two independent α -CDs. The environment of the tellurium containing cluster is similar to that observed in the compound **Re₆Se₈(α -CD)** where the tellurium cluster is also surrounded by four α -CDs which delimit a rectangle (Figure 3c). The dimensions of this rectangle are slightly bigger than that found in the compound **Re₆Se₈(α -CD)** (13.7 x 18.7 Å for **Re₆Te₈(α -CD)** and 14.1 x 17.5 Å for **Re₆Se₈(α -CD)**). This is due to a slight deviation of the *C*₃ axis of tellurium-containing clusters from the central CD axis (Figure 3c). Four cyano groups of each [Re₆Te₈(CN)₆]⁴⁻ interact with the outer wall of the macrocyclic host through hydrogen bonds. The stronger ones are observed between two cyano groups and closest hydroxyl of the secondary face, giving N...O distances of 2.72 Å. Two additional weakest hydrogen bonds involving cyano groups and hydroxyl group of primary faces (N...O = 3.1 Å) contribute further to the stabilization of the supramolecular network. These overall weak interactions between the [Re₆Te₈(CN)₆]⁴⁻ and α -CDs allow the formation of anionic 2D-sheet in the *ab* plane (Figure 3d). Two hybrid 2D-sheets

stack together through primary faces of CD, resulting in the formation of a hybrid ‘double layer’. In the 3D arrangement, this hybrid “double layer” alternates with a cluster-free CD layer generating a lamellar assembly stacked along the [001] direction (Figure 3d). The electric balance is ensured by the presence of potassium ions spanning CDs and cyano groups of clusters.

Figure 4: Views of the structural arrangement in the series $K_4\{[Re_6Q_8(CN)_6]@-(\beta-CD)_2\} \cdot 2(\beta-CD) \cdot nH_2O$ with $Q = S$ (**Re₆S₈@β-CD**), Se (**Re₆Se₈@β-CD**) and Te (**Re₆Te₈@β-CD**). a) View of the rhenium cluster partially embedded within two β-CDs exposing their primary faces. b) View of the unit cell and the stacking of the supramolecular sheet along the perpendicular direction to the *bc* plane.

Compounds **Re₆S₈@β-CD**, **Re₆Se₈@β-CD** and **Re₆Te₈@β-CD**. Structural analysis of $K_4\{[Re_6Q_8(CN)_6]@-(\beta-CD)_2\} \cdot 2(\beta-CD) \cdot nH_2O$ with $Q = S$ ($n = 25$), Se ($n = 21$), and Te ($n = 25$) (noted **Re₆S₈@β-CD**, **Re₆Se₈@β-CD** and **Re₆Te₈@β-CD**, respectively) reveals three isostructural compounds which contain the octahedral cluster $[Re_6Q_8(CN)_6]^{4-}$ embedded into two β-CDs (Figure 4a). This host-guest arrangement is different from the supramolecular inclusion complex previously observed with α-CD and $[Re_6S_8(CN)_6]^{4-}$. In fact, the $[Re_6Q_8(CN)_6]^{4-}$ interacts with the primary face instead of the larger rim (secondary face) of the cyclodextrins. The C_4 axis of the octahedral cluster deviates significantly from the β-CD central axis (23°). Consequently, the four equatorial cyano groups, sandwiched between both primary faces, interact non-equally with proximal H6 protons ($N \cdots C = 2.8\text{--}3.0 \text{ \AA}$). The two resulting cyano groups pointed to the host cavities slightly interact with the inner tori host ($N \cdots H-C = 3.0\text{--}3.2 \text{ \AA}$). In the crystal packing, the inclusion complex $\{[Re_6Q_8(CN)_6]@-(\beta-CD)_2\}^{4-}$ is stacked with two empty β-CDs through their secondary faces along [011] direction, giving a 0D tubular arrangement (Figure 4b). The cohesion within such supramolecular organization is mainly ensured by a network of hydrogen bonding that interconnects secondary faces of β-CDs ($O \cdots O = 2.7\text{--}3.2 \text{ \AA}$) giving bamboo like tubular arrangement. In addition to this hydrogen bonding network, potassium cations and water molecules are found between the tubular arrangements.

Summary of the host-guest structural features. The nature of the supramolecular arrangements built from cyclodextrins and rhenium based clusters depends on the size-matching between the macrocyclic host and the inorganic cluster. The types of inclusion complexes observed in solid state are summarized in Figure 5. The solid-state studies clearly indicate the $[Re_6Se_8(CN)_6]^{4-}$ and $[Re_6Te_8(CN)_6]^{4-}$ interact similarly with CDs while $[Re_6S_8(CN)_6]^{4-}$ shows a distinct behav-

our. In our previous study,⁹ we showed that rhenium based clusters interact strongly with γ-CD giving preferentially 1:2 supramolecular assemblies where the smaller cluster ($Q = S$), interacts with the primary faces of tori host, while the larger ones ($Q = Se$ or Te) are deeply embedded through the secondary faces. Sulphur containing cluster also interacts differently with α-CD than the larger clusters. Actually, we showed the smaller α-CD gives host-guest system exclusively with $[Re_6S_8(CN)_6]^{4-}$ through the secondary rim. From this observation, it appears clearly that Se and Te based clusters are too large to be embedded into the cavity of the α-CD. In the case of β-CD, all clusters adopt the same structural arrangement consisting with a host-guest arrangement involving a cluster unit and two CDs. In conclusion, we evidence the high propensity of the rhenium clusters $[Re_6Q_8(CN)_6]^{4-}$ and CDs to form hybrid networks. Depending on size-matching criteria, these networks result either from co-crystallization processes or from 1:2 inclusion complexes.

	$Re_6S_8(CN)_6^{4-}$	$Re_6Se_8(CN)_6^{4-}$	$Re_6Te_8(CN)_6^{4-}$

Solution studies

To get more insights within the supramolecular behaviour of cluster-CD system, solution studies of aqueous mixtures have been carried out using a set of complementary techniques including multinuclear NMR spectroscopy, ITC, cyclic voltammetry, ESI-MS spectrometry and circular dichroism.

NMR spectroscopy. The interaction of clusters $[Re_6Q_8(CN)_6]^{4-}$ ($Q = S, Se$ or Te) with the α- and β-CD has been investigated by 1H NMR titrations up to 4 equivalents of cluster per cyclodextrin (Figures S3-S8). Figure 6 compares the resulting end-point titration spectra obtained for the different CDs in presence of 4 equivalents of cluster. This analytical tool is sensitive enough to get insight about the nature of supramolecular interactions. It is worth to be mentioned that the NMR titration experiments show gradual variations of the 1H resonances depending on the ratio

Figure 6. ^1H NMR spectra of α - (left) and β -CD (right) with four equivalents of octahedral rhenium cluster $[\text{Re}_6\text{Q}_8(\text{CN})_6]^{4-}$ (Q = S, Se or Te) in D_2O . Concentration of organic host is fixed to 2 mM.

cluster/CD (see Figure S3-S8). This features fast exchange on the NMR time scale consistent with labile host-guest associations. Evolution of ^1H NMR spectrum in presence of four equivalents of cluster reveals contrasted behaviours related to the host-guest size-matching (see Figure 6).

In the case of α -CD, only tiny modifications of the organic host NMR signals are detected in presence of four equivalents of $[\text{Re}_6\text{Se}_8(\text{CN})_6]^{4-}$ or $[\text{Re}_6\text{Te}_8(\text{CN})_6]^{4-}$, consistent with very weak interactions. The situation differs for the sulphur-containing cluster $[\text{Re}_6\text{S}_8(\text{CN})_6]^{4-}$ showing a significant downfield shift for the protons H3, H5 and H6 in accordance with formation of host-guest complexes.

Besides, the ^1H NMR spectra of β -CD upon increasing concentration of all the clusters revealed continuous changes of chemical shifts (see Figure 6 and Supporting Information, Figures S6-S8). This observation suggests that all clusters interact with β -CD to give labile associations involved in fast chemical exchange regime. The most significantly affected chemical shift corresponds to the inner proton H3, and the shift amplitude increases in the following order $\text{Te} < \text{S} < \text{Se}$, which could be the fingerprint of a selective size-matching process. For instance, in presence of four cluster equivalents, the difference in chemical shift is 0.35, 0.5, and 0.2 ppm for S-, Se- and Te-derivative, respectively. These results would indicate predominant host-guest associations in solution occurring preferentially with the secondary face of the torus. However, the small downfield shifts of the proton H5 and H6 are also observed, that would indicate that these clusters are able to interact also with the primary face of β -CD. These undergoing changes in solution are probably due to versatile behaviour arising from close binding energies between primary and secondary rims of the β -CD.

All these ^1H NMR observations corroborate quite well conclusions arising from structural investigations: i) only the sulphur-containing cluster forms inclusion complexes with α -CD in solution, and ii) all clusters interact with the β -cavity in solution to give inclusion complexes. However, we observe some apparent discrepancies between crystal structures analysis and behaviours in solution. For instance, the clusters interact with the primary face of β -CDs in solid state, while NMR solution investigation indicates clusters are

mainly interacting with the secondary face through the H3 protons. Such an observation is rather consistent with close binding energies that favour interactions with secondary or primary faces depending either on the minimization of lattice energy in the solid state or on the solvent effect in solution.

^{77}Se and ^{125}Te NMR experiments have been carried out (Figures S9-S10). Tiny variation of the ^{125}Te NMR resonance ($\Delta\delta < 0.5$ ppm) is consistent with weak interactions between $[\text{Re}_6\text{Te}_8(\text{CN})_6]^{4-}$ and β -CD. Such situation differs significantly from γ -CD showing the deep embedment of the Te-clusters inside γ -CD cavity.⁹ Besides, $[\text{Re}_6\text{Se}_8(\text{CN})_6]^{4-}$ cluster undergoes a 4 ppm downfield shift of the ^{77}Se NMR resonance in presence of β -CD that highlights stronger supramolecular interactions. It is worth noting that about 4 ppm upfield shift in the ^{77}Se NMR was observed with γ -CD.⁹ This opposite trend in the ^{77}Se NMR spectra highlights probably different scenario in host-guest binding modes (i.e. partial *versus* deep encapsulation or primary *versus* secondary or 1:1 *versus* 1:2 complex type).

Isothermal Titration Calorimetry.

ITC investigations have been carried out to determine the thermodynamic parameters of the supramolecular complexation processes. The binding constants and changes of enthalpy $\Delta_r H^*$ and entropy $\Delta_r S^*$ of each cluster/CD system are given in Table 1, and compared to data previously obtained with the $[\text{Re}_6\text{Q}_8(\text{CN})_6]^{4-}/\gamma$ -CD system.⁹ ITC thermograms and isotherms are presented in Supporting Information (Figures S11 and S12). The ITC data have been analysed using one-site binding model for the binary systems $[\text{Re}_6\text{Q}_8(\text{CN})_6]^{4-}/\text{CD}$.

Firstly, ITC data show that the binding of rhenium clusters with α - or β -CD is an enthalpically driven process accompanied with an entropic penalty. This thermodynamic signature could correspond to the typical binding of chaotropic entities to CDs.^{7,9,10,12} Therefore, the main driving force of the supramolecular complexation would be the bulk water structure recovery from the solvation shell of the chaotropic clusters. Furthermore, increasing of enthalpic contribution along $[\text{Re}_6\text{Q}_8(\text{CN})_6]^{4-}/\text{CD}$ series is balanced by an increasing entropy penalty according to enthalpy-entropy compensation usually observed as a quasi-linear correlation (Figure 7a).¹

Table 1. Binding constants K involving rhenium octahedral clusters with native CDs (α -, β - and γ -CD) and associated thermodynamic parameters (in $\text{kJ}\cdot\text{mol}^{-1}$) at $T = 298\text{ K}$.

^a determined by ITC, ^b determined by ^1H NMR titration, ^c binding constant is too weak to be determined, ^d no significant heat release detected.

Secondly, we observe that binding constants K obtained with α - and β -CD are smaller than values observed for γ -CD. This is understood by considering i) the desolvation process of the guest by the macrocycle host and ii) the size/shape compatibility between both components of the inclusion complex. As observed in X-ray crystal structures (Figure 5), the small CDs (α - and β -CD) encapsulate partially the inorganic guest, unlike γ -CD gives deep embedment. In short, a deep inclusion process is expected to release a large number of ‘disordered’ water molecules, resulting in a larger entropic penalty (see Table 1 and Table S3). Actually, this desolvation effect is then directly dependent of the host-guest shape complementarity but also dependent on their respective size and on the extent of their interacting interface. The binding constants for the larger cluster, $[\text{Re}_6\text{Te}_8(\text{CN})_6]^{4-}$ vary strongly in α -, β -CD and γ -CD series. In fact, this cluster is too large to enter into the α - and β -CD but fits perfectly with γ -CD cavity size, resulting in the larger K_{11} stability constant ($K_{11} = 37\,700$).

A concomitant effect associated to the decreasing size of the cluster (from Te to S) weakens the host-guest supramolecular cohesion observed in the solid state with the significant increase of the shortest host-guest separations. Then a host-guest fitting geometrical parameter (noted R) can be introduced as the ratio between the average outer diameter of one face of the octahedral $\{\text{Re}_6\text{Q}_8\}$ core and the average inner diameter of the CD (see Figure 7b). Depending on the host-guest system, R parameter values spread from 0.82 to 1.5 enclosing $R = 1$, a value which is expected for the best host-guest matching. Actually, the tellurium-containing cluster/ γ -CD system is featured by the R value closest to 1 ($R = 0.97$) values while this supramolecular system exhibits the highest K_{11} value (see Figure 7c). It is worth mentioning that deviation of R value from 1 on both sides leads to host-guest systems exhibiting very low or moderate K_{11} values below 1000 M^{-1} .

Furthermore, geometrical disagreement should be enhanced by host-guest symmetry mismatching, for instance O_h for the cluster and C_7 for β -CD. These results demonstrate that a size-exclusion mechanism prevails within the host-guest

Figure 7. a) Enthalpy-entropy compensation plot for 1:1 cyclodextrin complexes with $[\text{Re}_6\text{Q}_8(\text{CN})_6]^{4-}$. b) Schematic representation showing the structural parameters used for the calculation of the host-guest structural fitting parameter R determined from the following equation: $R = D_{Q-Q}/D_{CD}$. c) Evolution of the one-site binding constant as a function of host-guest fitting parameter R .

recognition process favoured by both the solvent effects and optimization of attractive dispersion forces. Besides, full analysis of the thermodynamic data reveals that all the $[\text{Re}_6\text{Q}_8(\text{CN})_6]^{4-}$ clusters exhibit a chaotropic behaviour, identified as one possible main contributors within aggregation processes in aqueous solution.¹³ It should even worth mentioning that some of these species, such as the Keggin polyoxotungstate $[\text{PW}_{12}\text{O}_{40}]^{3-}$ or halide dodecaborate ions $[\text{B}_{12}\text{X}_{12}]^{2-}$ (with $\text{X} = \text{Cl}, \text{Br}$ or I) have been referred as “super-chaotrope” within the extended Hofmeister scale. Furthermore, in the halide dodecaborate series $[\text{B}_{12}\text{X}_{12}]^{2-}$ the chaotropic character has been correlated to the halide polarizability, increasing the chaotropic nature when X varies from Cl to I .¹⁰ Surprisingly, as shown in Figure 7a for the

Figure 8: Cyclic voltammetry of the $[\text{Re}_6\text{Q}_8(\text{CN})_6]^{4-}$ anions (0.5 mmol.L^{-1} , $2.5 \text{ mmol.L}^{-1} \text{ HClO}_4$ aqueous solution, glassy carbon working electrode, scan rate 50 mV.s^{-1}) in the presence of increasing amounts of α -CD (Q = S (a), Se (b) or Te (c)) or β -CD (Q = S (d), Se (e) or Te (f)).

$[\text{Re}_6\text{Q}_8(\text{CN})_6]^{4-}$ series, the magnitude of the chaotropic character varies as the inverse of the polarizability of the chalcogenide Q in the order $\text{S} > \text{Se} > \text{Te}$, while an opposite trend could be expected.⁹ Such an observation can be understood from antagonist influence arising from the six exposed cyano groups. Actually, as the σ donor capability of the Q ligands toward the Re centers increases from S to Te, the Re-C σ overlap weakens with direct consequence of increase of the cyano group polarization.⁴¹ Then, as the charge density decreases on the Q ligands from S to Te, ionic charge density at the six exposed cyano ligands increases concomitantly to cancel partially the expected chaotropic nature of the cluster.

Electrochemistry. The cyclic voltammograms of rhenium clusters show a reversible monoelectronic wave leading to the oxidized entities $[\text{Re}_6\text{Q}_8(\text{CN})_6]^{3-}$. In our previous study, we observed the encapsulation of rhenium clusters within γ -CD affects strongly the electrochemical signature of guest.⁹ Such effect is commonly observed when the reduced and the oxidized states exhibit a different affinity with a macrocyclic host.^{5,9,42–44} Herein we investigate the effect of α - and β -CD on the redox properties of $[\text{Re}_6\text{Q}_8(\text{CN})_6]^{4-}$. Figure 8 shows the cyclic voltammograms of rhenium clusters $[\text{Re}_6\text{Q}_8(\text{CN})_6]^{4-}$ in presence of various amounts of cyclodextrins (from 0 to 10 equivalents of CDs) in 2.5 mM perchloric acid aqueous solution. Almost no modification of cyclic voltammograms is observed in the experiments involving the $[\text{Re}_6\text{Se}_8(\text{CN})_6]^{4-}$ and $[\text{Re}_6\text{Te}_8(\text{CN})_6]^{4-}$ with α -CD as well as for $[\text{Re}_6\text{Te}_8(\text{CN})_6]^{4-}$ with β -CD. These results confirm the lack of any significant host-guest interactions with the reduced species and indicate that no more interaction holds with the oxidized species. Conversely, the interaction of sulphur-based cluster with α -CD or β -CD is featured by a gradual decreasing of the half-wave potential $E_{1/2}^{\text{app}}$ which is also associated to a weak decrease of the peak currents. Similarly the selenium based cluster exhibits the same behaviour with β -CD. The variation of the half-wave potential indicates that cyclodextrin is involved within the one electron transfer process, consistent with an increase of the host-guest affinity through the cluster oxidation. Further-

more, the substantial reduction of the peak currents due to the decrease of the diffusion coefficient is the fingerprint of a supramolecular process induced by the oxidation reaction.

In the electrochemical conditions (0.5 mM cluster solution and up to 10 eq. of CD), the speciation diagram established from the stability constants shows that the 1:1 inclusion complex is the predominant reduced species. Then the corresponding redox reaction should be expressed as Equation 1 and the related Nernst equation given in Equation 2 could be considered.⁹

$$E_{1/2}^{\text{app}} = E_{1/2}^{\text{CD}} + 0.059 pCD \quad (2)$$

where $pCD = -\log[CD]$ and $E_{1/2}^{\text{CD}}$ is the half-wave potential of the redox couple $[\text{Re}_6\text{Q}_8(\text{CN})_6@2CD]^{3-}/[\text{Re}_6\text{Q}_8(\text{CN})_6@CD]^{4-}$. However, it must be worth mentioning that ClO_4^- ions from electrolyte compete with the cluster complexation since perchlorate anions are known to interact weakly with α -CD ($K = 16\text{--}66 \text{ mol.L}^{-1}$)^{45–48} and β -CD ($K = 9\text{--}16 \text{ mol.L}^{-1}$).^{48,49} Herein, this competitive effect becomes negligible as concentration of perchloric acid remains below 2.5 mM HClO_4 . In such conditions, the half-wave potentials $E_{1/2}^{\text{CD}}$ vary linearly as a function of pCD with slopes close to the expected value of about 59 mV per pCD unit (Figure S13). For higher concentration in perchloric acid (up to 25 mM), competition processes between clusters and ClO_4^- anions change significantly the clusters speciation which reduces the half-wave potential dependency upon the pCD (Figure S14–S16).

Table 2. Calculated global formation constant related to Equation 3.

Q	CD	$\beta'_2(\text{M}^{-2})$	Refs
S	α -CD	$2.3 \cdot 10^6$	This work
	β -CD	$3 \cdot 10^6$	This work
	γ -CD	$2.2 \cdot 10^7$	⁹
Se	β -CD	$1.6 \cdot 10^6$	This work

The half-wave potential $E_{1/2}^{CD}$ of each redox couple $[Re_6Q_8(CN)_6@2CD]^{3-}/[Re_6Q_8(CN)_6@CD]^{4-}$, CD has been determined from the Equation 1 (Table S4). The global formation constants β'_2 related to Equation 3 have been determined (Table 2) using the Equation 4 where $K_{1:1}$ corresponds to the stability constant of the reduced forms determined by ITC, $E_{1/2}^0$ is the standard potential of the redox couple $[Re_6Q_8(CN)_6]^{3-}/[Re_6Q_8(CN)_6]^{4-}$ and $E_{1/2}^{CD}$ is the redox potential associated to the redox couple involved in Equation 1.

$$E_{1/2}^0 = E_{1/2}^{CD} + 0.059 \log \frac{\beta'_2}{K_{1:1}} \quad (4)$$

This result highlights the high affinity of the oxidized species for CDs able to produce the 2:1 complexes. The calculated binding constants β'_2 for sulphur cluster with CDs lie in the same order of magnitude, showing the weak selectivity as observed for its reduced homologues, and then rather consistent with a predominant solvent effect.

ESI-MS. ESI-MS is useful for investigating supramolecular recognition competition reactions.^{50,51} For each rhenium cluster, competitive host-guest complexation in ESI-MS has been carried out on aqueous mixtures containing two equivalents of each native CD (α -, β -, and γ -CD). Although the ionization process involves oxidation of the cluster complexes $[Re_6Q_8(CN)_6]^{4-}$ into $[Re_6Q_8(CN)_6]^{3-}$, ESI-MS study nicely corroborates the conclusions arising from solution investigations on the reduced derivatives. This study indicates that sulphur based cluster forms supramolecular adducts with all cyclodextrins, unlike the selenium and the tellurium derivatives which are mainly bound to larger CDs. All ESI-MS spectra and their detailed interpretation are provided in Supporting Information (see, Figures S17-S19 and Tables S5-S7). Briefly, it was found that sulphur derivative forms 1:1 adducts with each cyclodextrin ($\{[Re_6S_8(CN)_6](\alpha-CD)\}^{3-}$ ($m/z = 833.93$), $\{[Re_6S_8(CN)_6](\beta-CD)\}^{3-}$ ($m/z = 887.94$) and $\{[Re_6S_8(CN)_6](\gamma-CD)\}^{3-}$ ($m/z = 941.97$)). In case of Se-containing cluster complexation forms only with β - and γ -CD ($\{[Re_6Se_8(CN)_6](\beta-CD)\}^{3-}$ ($m/z = 1013.78$) and $\{[Re_6Se_8(CN)_6](\gamma-CD)\}^{3-}$ ($m/z = 1067.79$)) with two times more intense mass-peaks for γ -CD. The tellurium containing cluster forms complex only with γ -CD ($\{[Re_6Te_8(CN)_6](\gamma-CD)\}^{3-}$ ($m/z = 1197.10$)).

Circular dichroism. Induced circular dichroism is generally observed when achiral guest interacts specifically with chiral host such as cyclodextrins,^{52,53} silica nanohelices⁵⁴ or proteins.⁵⁵ Circular dichroism investigations have been carried out on aqueous solutions containing $[Re_6Q_8(CN)_6]^{4-}$ and large excess of CDs. The circular dichroism spectrum of $[Re_6Te_8(CN)_6]^{4-}$ in presence of γ -CD shows a strong negative Cotton signal at 212 nm, a strong positive signal located at 228 nm, and two weak and broad negative signals at around 248 and 300 nm (Figure 9). In contrast, this cluster exhibits no signal in presence of α - and β -CD (Figure 9). The cluster $[Re_6Se_8(CN)_6]^{4-}$ shows similar features than

$[Re_6Te_8(CN)_6]^{4-}$. In fact, Se- derivative exhibits no chirality induction in presence of small CDs, while two strong Cotton peaks located at 215 nm (negative signal) and 237 nm (positive signal) are detected for aqueous mixture of Se based cluster and γ -CD (Figure S20). A different situation occurs on sulphur based cluster in presence of γ -CD, which is probably due to its distinct supramolecular behaviour, since only weak positive Cotton signals are observed at 224 and 281 nm (Figure S20). As for Se and Te derivatives, no chirality induction takes place with $[Re_6S_8(CN)_6]^{4-}$ in presence of α - and β -CD. The circular dichroism investigation reveals that the chirality induction from cyclodextrin to the cluster is clearly correlated with the specificity of the host-guest interactions in solution. Actually, as usually observed, the transfer of chirality arises from deep host-guest inclusion and therefore it occurs exclusively in presence of largest cyclodextrin (γ -CD).

Figure 9: Comparison of the circular dichroism spectra of tellurium derivative in presence of cyclodextrins. Such results underline that deep inclusion of the cluster inside γ -CD provokes a remarkable chirality induction.

Conclusions

Herein, we reported on the systematic investigation of the cyclodextrin size cavity effect (α -, β - and γ -CD) toward the supramolecular complexation of octahedral rhenium clusters $[Re_6Q_8(CN)_6]^{4-}$ ($Q = S, Se, \text{ and } Te$). Single-crystal X-ray diffraction analysis allowed determining structural arrangements for all CD-cluster combinations showing either co-crystallized hybrid systems or host-guest supramolecular complexes. In addition, aqueous solution behaviour has been studied carefully through a set of complementary techniques (NMR, ESI-MS, ITC, electrochemistry and circular dichroism). These results underline that $[Re_6Q_8(CN)_6]^{4-}$ exhibits contrasting behaviour upon the host-guest binding, allowing a selective molecular recognition of the clusters by the appropriate cyclodextrin. The sulphur derivative which is the strongest water-structure breaker in the cluster series interacts with all CDs forming 1:1 host-guest complex having comparable stability constant in solution, indicating the self-assembly process is mainly driven by desolvation process of

the clusters. On the other hand, the intermediary-sized cluster $[\text{Re}_6\text{Se}_8(\text{CN})_6]^{4-}$ interacts with both β - and γ -CD while the larger $[\text{Re}_6\text{Te}_8(\text{CN})_6]^{4-}$ interacts exclusively with the γ -CD giving strongest inclusion complex featured by two orders of magnitude higher stability constant. Such results evidence that selectivity of the aggregation processes arises from a size-exclusion mechanism that requires at least partial host-guest inclusion to generate stable assembly.
