ABSTRACT

The presence of pharmaceutical residues in water resources is a critical issue for the production of drinking water, even though trace concentrations are mostly encountered. The adsorption of eight micropollutants, in mixture, onto a microporous activated carbon fiber cloth was investigated. For each compound, the kinetics and isotherms of adsorption were studied in batch reactors with ultrapure water, groundwater and half-diluted groundwater. Experimental data were generated and compared to values calculated by the association of Ideal Adsorbed Solution Theory (IAST) model and the Homogeneous Surface Diffusion Model (HSDM). The impact of the nature and the content of Natural Organic Matter (NOM) was modeled considering an Equivalent Background Compound (EBC). The presence of NOM in the groundwater is largely detrimental for the adsorption of trace micropollutants.

Adsorption of pharmaceutical residues on activated carbon fiber cloths

Equivalent Background Compound versus micropollutants

List of symbols

A	Interfacial surface area (L^2L^{-3})
b	Parameter of the Langmuir – Freundlich equation ($L^{3/n}M^{-1/n}$)
Bi	Biot number (-)
C_i	Concentration of the component (i) in the multicomponent solution (ML^{-3})
C_i^o	Concentration of the component (i) in the monocomponent solution (ML^{-3})
C_{ei}	Concentration of the component (i) in the multicomponent solution at the equilibrium (ML^{-3})
C_0	Initial concentration (ML^{-3})
D_s	Surface diffusion coefficient (L^2T^{-1})
d_p	Diameter of the particle (L)
k_f	External mass transfer coefficient (LT^{-1})
m	Mass of adsorbent (M)
n	Parameter of the Langmuir – Freundlich equation (-)
n_c	Number of components in the solution
q_{ei}	Concentration of the component (i) in solid phase in multicomponent adsorption at equilibrium (MM^{-1})
$q_{ei,mod}$	Simulated concentration of the component (i) in solid phase in multicomponent adsorption at equilibrium (MM^{-1})
$q_{ei,exp}$	Experimental concentration of the component (i) in solid phase in multicomponent adsorption at equilibrium (MM^{-1})
q_i	Concentration of the component (i) in solid phase in multicomponent adsorption (MM^{-1})
q_i^o	Concentration of the component (i) in solid phase in monocomponent adsorption (MM^{-1})
q_m	Maximum adsorption capacity of the component (i) (MM^{-1})
q_T	Total concentration in the solid phase (MM^{-1})
R	Ideal gas constant ($LT^{-2}\square^{-1}$)
r_p	Radius of fiber (L)
T	Temperature (\square)
t	Time (T)
V	Volume of the solution (L^3)

z_i Molar fraction in adsorbed phase

\square_m Spreading pressure in the multicomponent system (MT^{-2})

\square_i Spreading pressure of the component (i) in the monocomponent system (MT^{-2})

\square_p Apparent density of particle (ML^{-3})

1 Introduction

The contamination of aquatic systems by pharmaceutical residues is now a major concern for the environment and risk assessments are necessary for human health [1][2][3][4]. All aquatic compartments are impacted. In European rivers, Loos *et al.* [5] have detected diclofenac in 83 % of their samples. The maximum concentration was found to be 11 ng.L^{-1} for de Jesus Gaffney [1]. Likewise, carbamazepine and acetaminophen were identified and quantified at concentrations of 200 ng.L^{-1} in surface waters [6]. More recently, Bazus *et al.* [7] have monitored 37 pharmaceutical residues in 8 surface waters and drinking waters, in western France, and the highest drug concentrations were reported for ketoprofen, hydroxy-ibuprofen, acetaminophen, caffeine and danofloxacin. Despite these concentrations in aquatic systems, as resources for the production of drinking waters, risks for human health were considered negligible [1] [8]. However, risk assessments are still discussed following some authors [9] [10].

Adsorption-based technologies are recognized as efficient, promising treatment alternatives that are widely used in water and wastewater treatment for the removal of organic micropollutants such as pharmaceutical residues and pesticides [11] [12] [13]. In practice, granular activated carbon (GAC) [14] and/or powdered activated carbon (PAC) are used to eliminate organic pollutants. According to Rigobello *et al.* [15] and Sotelo *et al.* [16] the adsorption capacities of diclofenac at high concentrations, onto granular activated carbon are about 230 mg.g^{-1} for a residual aqueous concentration of 40 mg.L^{-1} . For carbamazepine, Cai and Larese-Casanova [17] found capacities of 200 mg.g^{-1} onto granular activated carbon for a residual concentration of 0.5 mg.L^{-1} .

Activated carbon fiber cloths (ACFC) have been studied for water treatment [18] [19]. The advantages of such textiles are their high specific surface areas, predominantly microporous texture and large adsorption capacities [20] [21]. Therefore, ACFC were more efficient in terms of adsorption rate and selectivity than granular activated carbon for the removal of aromatic compounds [16] [22]. However, to our knowledge, few studies have dealt with the adsorption of pharmaceutical residues and pesticides onto ACFC [23] [24], especially at trace concentrations. However, supplementary informations are required in order to understand how activated carbon cloths behave at low concentrations of pollutants in presence of natural organic matter.

Nowadays, adsorption processes are most often designed on the basis of the amount adsorbed at equilibrium with the inlet concentration of the micropollutants. Therefore, isotherms of adsorption should be carefully modeled taking into account experimental errors, the type of model and error function [25] [26] [27]. Special care should be paid when dealing with trace concentrations and the extrapolation of isotherm models [28]. Even with realistic and relevant adsorption capacities at trace concentrations, the impact of the nature of Natural Organic Matter (NOM) should be considered, particularly in the presence of low molecular components of NOM [29]. Moreover, adsorption capacities from isotherms conducted in batch reactors were shown to overestimate the adsorption capacities for breakthrough curves [30]. Although the impact of NOM is complex, two main mechanisms could be distinguished: the site competition with a strongly competing equivalent NOM compound and/or the pore blockage occurring with larger NOM compounds [31][32].

The aim of this study is to evaluate the efficiency of ACFC for the removal of 8 emerging pollutants in mixture. Batch reactors were carried out to study the kinetics and adsorption capacities of ACFC to remove micropollutants in different kinds of waters (ultrapure, ground water and half diluted groundwater). Kinetic experimental data were compared to the most frequently models used (HSDM) in a multicomponent solution (IAST model).

2 Materials and methods

2.1 Materials

2.1.1 Organic compounds

The targeted compounds – acetaminophen, caffeine, carbamazepine, diclofenac, ofloxacin, ibuprofen, mecoprop, bisphenol A and benzotriazol – were all purchased from Sigma-Aldrich (purity > 98 %). The physicochemical properties and molecular structures of the compounds are listed in Table 1. Stock solutions (10 mg.L⁻¹) were prepared by dissolving the commercial standard in ultrapure water (UPW) provided by an ElgaPureLab System (18.2 MΩ.cm). The experiments were carried out at low concentrations (C₀ = 10 µg.L⁻¹). The experiments were achieved respectively in ultrapure water (UPW), groundwater (GW) and groundwater diluted (1/2 vol.) by ultrapure water (GW/2).

Analyses of the selected compounds were performed using UHPLC with an Acquity system (Waters) coupled with a tandem mass spectrometer (Quattro Premier, Micromass), the method was extensively describe elsewhere [31] [32]. Briefly, the chromatographic system included a 2777 autosampler (Waters) equipped for dual on-line solid phase extraction (on-line SPE) with HLB cartridges. 5 mL of sample was loaded onto the HLB cartridges using a large volume injection loop and a quaternary solvent pump (QSM – Waters). After the loading and cleaning steps, HLB cartridges were connected to the BEH C18 analytical column (100 x 2.1 mm x 1.7 µm, Waters) thermostatic at 45°C. The binary gradient consist of a mixture of acetonitrile as mobile phase A, and acetonitrile/water/formic acid (10:90:0.1, v/v/v) as mobile phase B. The separation was initiated at a constant flow of 0.4 ml.min⁻¹,

followed by a decrease in B to 10 % within 7 min. This composition was then maintained for 10 min and returned to the initial composition.

Mass spectrometry was used with an electrospray ionization source in positive or negative mode with a capillary voltage of 3 kV and nitrogen as the nebulizer and drying gas. The cone gas flow and the desolvation gas flow were set at 50 L.h⁻¹ and 750 L.h⁻¹, respectively. The source temperature and desolvation temperature were 120°C and 350°C, respectively. The multiple reaction monitoring (MRM) mode was used for the quantification of all compounds. Retention time, MRM transitions, cone voltage and collision cell energy are summarized in Table 1. To avoid matrix effects, quantification has been done using standard addition method previously described [33].

2.1.2 Ground water compositions

Groundwater (GW) came from infiltration in the well located on the campus of the Ecole Nationale Supérieure de Chimie de Rennes, France. Seasonal analyses were performed for the total organic content (DOC). The DOC was shown to vary from 1.5 and 5.7 mgC.L⁻¹. As illustrated in Table 2, the resistivity of the GW is relatively high and indicates that the minerals of water were quite low. GW was filtered through cellulose membranes (0.7 μm), to remove suspended solids and colloids before use. . The characteristics of ultrapure and groundwater are presented in Table 2.

Table 2 : Physicochemical properties of waters (values in brackets are seasonal standard deviations)

	Ultrapure water (UPW)	Groundwater(GW)
pH	6.8	6.4 (0.1)
Resistivity (M Ω .cm)	18.2	0.5 (0.02)
Absorbance UV ₂₅₄ (cm ⁻¹)	< 0.003	0.039 - 0.057

2.1.3 Activated carbon fiber cloth (ACFC)

The ACFC (commercial name: KI-P-1200) was supplied by Dacarb (Asnières-sur-Seine, France). It was washed as received in ultrapure water to remove any dissolved contaminants and/or fine particles and then dried at 120 °C prior to the experiments. The physical and chemical characteristics of the ACFC are given in Table 3. The physisorption of nitrogen at 77 K (Autosorb, Quantachrome Instruments) was used to determine the specific internal surface area (multi-point BET method in the range of relative pressures 0.01 to 0.1), the total pore volume (relative pressure of 0.995), the micropore volume and the average pore size (Quenched Solid State Density Functional Theory, QSDFT) [34][35]. In addition, the Boehm titration method was used to quantify the surface functional groups [36]. The ACFC possesses a highly microporous texture (over 90 % of the total pore volume) and few functional groups in comparison to common granular activated carbons [37]. This specificity was confirmed by the residual pH (measured after 24 h in ultrapure water), which was close to neutrality and in agreement with the balance between acidic and basic groups. These characteristics are summarized in Table 3.

Table 3 : Physical and chemical properties of the ACFC

Textural properties from N ₂ adsorption at 77 K	
Specific surface area (m ² .g ⁻¹)	1615

2.2 Adsorption kinetics and isotherms

Kinetic curves of adsorption were performed for all compounds in mixture, both in ultrapure and natural ground waters. For that purpose, 10 L reactors were used and the initial concentration was 10 μg.L⁻¹ of each compound. Preliminary experiments demonstrated that inter-component adsorption competition was not significant if the initial concentration was lower than 10 μg.L⁻¹ (as illustrated on Figure 1 – example for acetaminophen).

Figure 1. Adsorption of acetaminophen in UPW onto ACFC
(in single-component solution and in mixture)

The pH was maintained at 7.5 using hydrogen carbonate buffer and did not vary more than 0.1 pH unit between the initial and final time of the experiment. A temperature of 25 °C was kept constant using a thermostatic bath. A constant mass of ACFC (20 ± 0.2 mg) was then incorporated and the reactors were tightly sealed and homogenized using a magnetic stir bar at 400 rpm. The supernatant were filtered using a 0.2 μm GHP Acrodisc filter prior to analysis by SPE-UPLC/ MS-MS in order to determine the residual concentration (C_i) and adsorption capacities (q_i) according to the mass balance.

2.3 Modelling of multicomponent adsorption

The significant content of NOM in the natural water implied taking into account the competition of adsorption between the target compounds and the NOM. Competitive adsorption equilibria were modeled using the ideal adsorbed solution theory (IAST) (see equations Table 4), originally established by Radke and Prausnitz [38] for dilute aqueous solutions. Strictly, IAST requires the individual isotherm model for each component. However, assuming a non-interaction between molecules at low concentrations in mixture in ultrapure water, we consider the data obtained in these

conditions as individual isotherm values for each component. On one hand, the Langmuir-Freundlich model was used for each micropollutant, with parameters adjusted independently. On the other hand, the adsorption of NOM has to be described through an isotherm too. One possibility is to implement a single isotherm for pure NOM (for instance, measuring the residual DOC content after adsorption onto activated carbon). Another approach was used in this study. Indeed, NOM was considered as a single competing compound for the adsorption of each micropollutant. This methodology enables the distinction between the target compounds since NOM can have different impacts depending on the target compound (different locations in the porosity, pore blockage, modifications of the affinity between the adsorbate and the carbon surface). Consequently, the approach consists in representing NOM as an Equivalent Background Compound (named EBC) [39][40]. The competition becomes a co-adsorption between the target pollutant and the EBC [39][41][42][43][44]. In this case, the Langmuir-Freundlich equation was applied to the adsorption of the EBC and consequently, three parameters (q_m , b and n) should be fitted. Moreover, the initial concentration of the EBC is unknown. In order to improve the reliability of the adjustment procedure, adsorption isotherms were carried out in ground water as well as in half-diluted groundwater (which corresponds to an initial concentration of the EBC divided by 2).

Furthermore, in combination with the IAST, the homogeneous surface diffusion model (HSDM) [45] (Table 5) was used to describe the kinetics of adsorption. The inner diffusion equation for a sphere was used in the set of equations. In fact, the ACFC has a complex geometry with contacts between yarns formed from fibers. The external surface is difficult to define. It has to be stressed that the HSDM was used using the yarn as the elemental geometry for mass transfer, although the ACFC has a dual scale with yarns of 430 μm , made themselves of 10 μm fibers. Previous work concluded that external mass transfer was occurring at the outer surface of the yarn [27]. The Langmuir-Freundlich as the isotherm model was applied. This model was the most predictive model among 3 tested models (Freundlich, Langmuir and Langmuir-Freundlich equations) [27].

The calculations and applications of HSDM and IAST were performed with a software developed previously [40].

Equation	n°	Role
$q_T = \sum_{i=1}^n q_i$	1	Concentrations in the solid phase
$z_i = \frac{q_i}{q_T}$	2	Molar fraction in the adsorbed phase
$\frac{1}{q_T} = \sum_{i=1}^n \frac{z_i}{q_i^0}$ $\sum_{i=1}^n \frac{q_i}{q_i^0} = 1$	3	Non selectivity of the homogeneous surface
$C_i = z_i C_i^0(\pi_m)$	4	Ideal solution behavior
$\pi_i(C_i^0) = \pi_m = \frac{RT}{A} \int_0^{C_i^0} \frac{q_i^0}{C_i^0} dC_i^0 = \frac{RT}{A} \int_0^{q_i^0} \frac{d \ln C_i^0}{d \ln q_i^0} dq_i^0$	5	Equality of spreading pressure of mixture versus pure ideal solution
$q_i^0 = f(C_i^0)$ $\frac{q_{ei}}{q_{mi}} = \frac{(bC_{ei})^n}{1 + (bC_{ei})^n}$	6	Isotherm adsorption equation Langmuir-Freundlich equation

Table 4 Equations for the Ideal Adsorbed Solution Theory (IAST)

Equation	n°	Role
$\frac{dc_i}{dt} V = M \frac{dq_i}{dt}$	7	Mass balance for batch test
$q_i = \frac{3}{(d_p/2)^3} \int_0^{d_p/2} q(r_p, t) r_p^2 dr_p$	8	Average concentration in solid phase

Table 5 Set of equations for the Homogeneous Surface Diffusion Model (HSDM)

3 Results

3.1 Kinetics of adsorption

Kinetic studies are essential to determine the required time to reach the equilibrium especially in ACFC where the kinetics are very fast compared to activated carbon or powder due to a large external surface [18] [19]. Moreover, the change in aqueous concentration against time was used to compute the mass transfer coefficients for each pollutant/adsorbent system. Matthews and Weber [46] proposed a two-step resistance. This homogeneous surface diffusion model (HSDM) supposes that the two limiting steps are the diffusion through the external layer surrounding the particle and surface diffusion inside the porosity. Thus, two coefficients can be calculated (i) K_f , which represents the external mass transfer, and (ii) D_s , which corresponds to the surface diffusivity. For each adsorbate/adsorbent couple studied, these two coefficients were calculated in ultrapure and half diluted groundwater and non-diluted groundwater water (Table 6) using an iterative optimization procedure which consists to minimize the error function ($E = \frac{1}{n} \sqrt{\left(\frac{q_i - q_{i\ mod}}{q_i}\right)^2}$) using the excel solver function [27].

Figure 2 shows the kinetics of adsorption in ultrapure water (UPW), ground water (GW) and groundwater diluted by two with ultrapure water (GW/2) with a starting concentration of $10 \mu\text{g.L}^{-1}$. As observed for the carbamazepine, some compounds were largely impacted by the presence of NOM, and these kinetic competition effects were similarly observed with diclofenac, caffeine, acetaminophen and ibuprofen. At the opposite, the rate of adsorption of benzotriazole, mecoprop and bisphenol A was slightly reduced in the presence of NOM. It clearly indicates that competitions for adsorption sites as well as pore blocking depend on the nature of micropollutants as shown by Snoeying and Coll. [47] [48].

Figure 2. Kinetics of adsorption of the 8 micropollutants ($C_0 = 10 \mu\text{g.L}^{-1}$) in ultrapure, diluted (1/2) groundwater and groundwater (Line corresponds to the prediction with the IAST - HSDM models)

In Table 6, considering the Biot numbers (dimensionless ratio of the rate of external transfer to the surface diffusion), two situations occurred. If Biot numbers were higher than 500 (for example, for carbamazepine or ibuprofen in ultrapure water), superficial diffusion was the only limiting mechanism. For these cases, the coefficient K_f had no statistical significance and there was no resistance to mass transfer in the boundary layer around the yarns. If Biot numbers were between 1 and 100, both mechanisms (external and inner diffusion) co-existed as limiting steps for the mass transfer. From data summarized in Table 6, four behaviors could be distinguished in the presence of NOM:

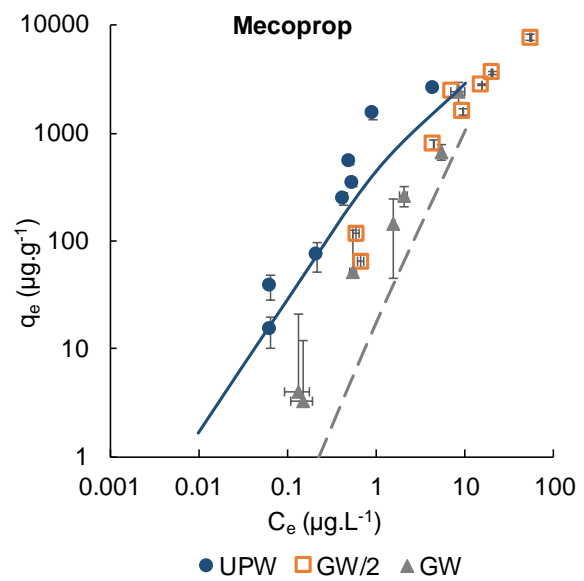

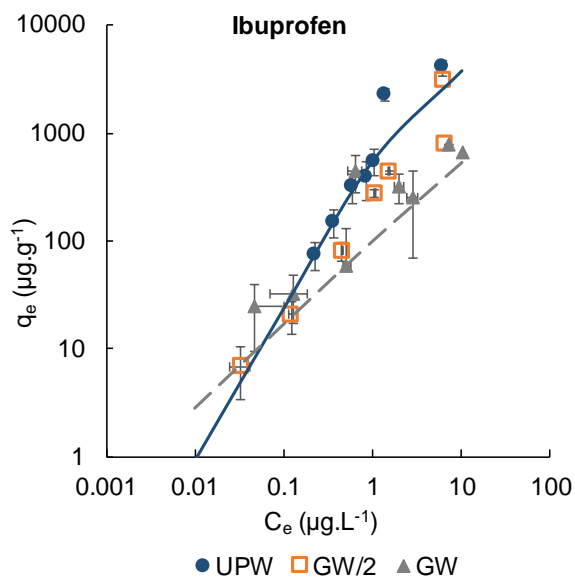

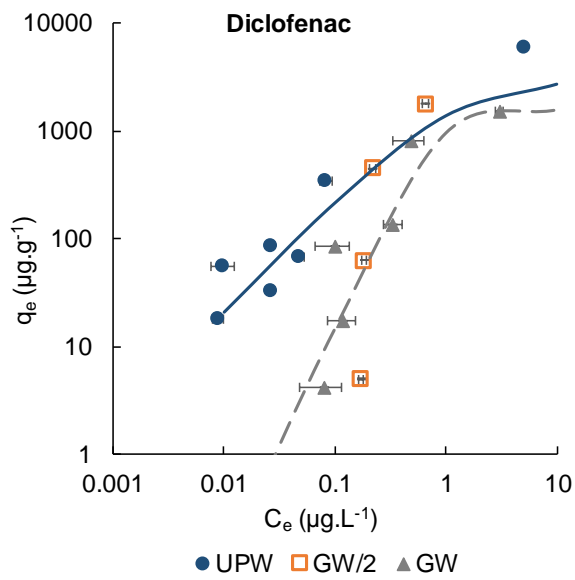

- For mecoprop, acetaminophen and benzotriazole, NOM had a negligible influence on Biot numbers. Regardless of the aqueous matrix, both mechanisms exist.
- Bisphenol A exhibited Biot number higher than 100, in both ultrapure and natural waters (i.e. in the presence or absence of NOM). Then, superficial diffusion was the only limiting mechanism.
- For carbamazepine and diclofenac, in ultrapure water, values were between 1 and 100, whereas, in natural water, Biot number became larger 100, and superficial diffusion became the limiting mechanism when NOM was competing for adsorption.
- For caffeine and ibuprofen, the opposite behavior was found with only surface diffusion ultrapure water, and the addition of external mass transfer resistance in the presence of NOM.

In Table 6, the surface diffusivities were shown to remain in the same order of magnitudes, and did not depend on the presence or absence of NOM [42] [43]. We assume a pore clogging due to NOM as shown in several previous works [47] [48] and not a real adsorption competition in the same sites between micropollutant and NOM. The only exception is diclofenac, for which the surface diffusivity decreased from $1.3 \cdot 10^{-9}$ to $4.2 \cdot 10^{-12} \text{ m}^2 \cdot \text{s}^{-1}$ from ultrapure to ground waters, respectively.

3.2 Isotherms of adsorption

Isotherms of adsorption were determined in ultrapure water (UPW), in ground water diluted two times by UPW (GW/2) and undiluted ground water (GW). The isotherm curves are presented on Figure 3. Each isotherm was modeled using the Langmuir-Freundlich model (Tables 7 and 8) ⁴⁹. Its parameters were adjusted by minimizing the relative error (E) (see equation 15 between simulated ($q_{ei,mod}$) and experimental ($q_{ei,exp}$) data according to the equation 1 and 2 [27]. In case of natural groundwater, the IAST was used in which the NOM was considered as an EBC.

$$E = \frac{1}{n} \sum_{i=1}^n \frac{|q_{ei,mod} - q_{ei,exp}|}{q_{ei,exp}} \quad (15)$$

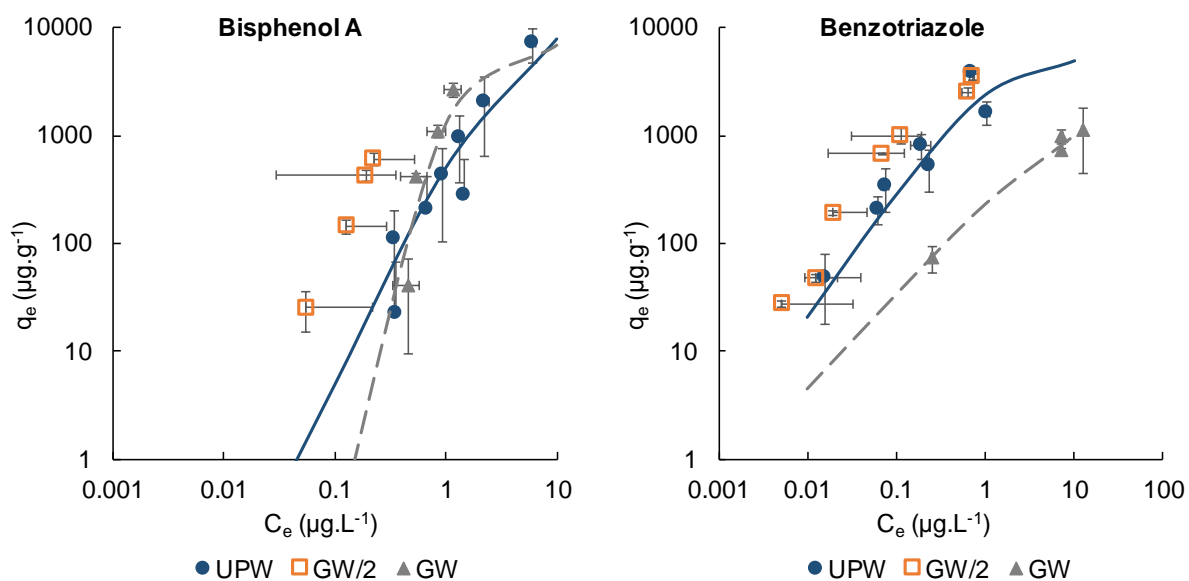

Figure 3 : Isotherms of adsorption of 8 micropollutants in ultrapure, diluted groundwater (1/2) and ground waters. Initial concentrations between 10 $\mu\text{g/L}$ and 10 mg/L . Lines correspond to the IAST model.

The adsorption capacities found previously at high concentrations were found previously around 200 – 250 mg/g for a concentration at equilibrium close to 20 – 40 mg/L [15] [16] [17]. In the present study, the adsorption capacities at very low concentration in the solution (Figure 3) are of the order of a few hundred $\mu\text{g g}^{-1}$ for a concentration in the solution at the equilibrium ranging 10 to 0.01 $\mu\text{g/L}$. From Figure 3, two types of results are shown. On one hand, for carbamazepine, Ibuprofen and benzotriazole, the impact of NOM was negligible for diluted ground water whereas the impact was important when non-diluted ground water was used. In those cases, the competition with NOM exhibited a threshold effect, *i.e.* the NOM content should exceed a certain amount for adsorption competitions to take place [40]. On the other hand, for caffeine and mecoprop, the impact of NOM was gradual when shifting from diluted to non-diluted ground water.

In order to assess the impact of NOM on adsorption capacities, it was chosen to compare the capacities for a given residual concentration of each micropollutant (0.1 $\mu\text{g/L}$). Results are gathered in Table 7.

Table 7 : Adsorption capacities for a residual concentration of 0.1 µg.L⁻¹ and impacts of natural water

	UPW		GW/2		GW	
	q ads (µg.g ⁻¹)	q ads (µg.g ⁻¹)	Impact	q ads (µg.g ⁻¹)	Impact	
Caffeine	767 ± 81	176 ± 23	[+++]	19 ± 8	[++++]	
Acetaminophen	794 ± 72	17 ± 5	[++++]	43 ± 12	[++++]	
Diclofenac	214 ± 43	1 ± 0.5	[++++]	2 ± 1	[++++]	
Carbamazepine	79 ± 13	80 ± 10	[-]	17 ± 9	[+++]	
Ibuprofen	24 ± 5	21 ± 4	[-]	17 ± 5	[++]	
Mecoprop	29 ± 5	3 ± 1	[++++]	0.2 ± 0.1	[++++]	
Benzotriazole	286 ± 25	191 ± 22	[++]	33 ± 10	[++++]	
Bisphenol A	5 ± 1			0.2 ± 0.1	[++++]	

$$Impact = \frac{q_{e,UPW} - q_e}{q_{e,UPW}} * 100$$

[-] No variation in comparison to UPW

[+] Decrease of adsorption capacity from 10 to 25 %

[++] Decrease of adsorption capacity from 25 to 50 %

[+++] Decrease of adsorption capacity from 50 to 75 %

[++++] Decrease of adsorption capacity from 75 to 100 %

Results in Table 8 show an important decrease of adsorption capacities in ground water, i.e., in the presence of NOM. For most of compounds, the diminution is over 75 %. However, behaviors in natural water are very different from one micropollutant to another. For example, for diclofenac and mecoprop, natural organic matter caused a reduction of 98 % of adsorption capacities. The Langmuir-Freundlich parameters (Table 7) in ground water correspond to the “EBC” and the initial concentration C_0 (mg DOC/L) is the concentration of organic matter which was in competition with each pollutants. These values of C_0 are very similar and close to 20 mg DOC/L.

In order to appreciate the impact of EBC on the adsorption of target molecules, a simulation of NOM adsorption was performed as shown in Figure 4. For a value of 1 mgDOC/L, we are already in the plateau of the curves. As a reminder, the initial concentration of COD in groundwater is about 2.9 mg DOC/L. Whatever the micropollutant, the values of adsorption capacity at the equilibrium are of the same order of magnitude excepted in the presence of Mecoprop at lower concentration in solution. However, comparing the adsorption capacities (q_m) in Table 8, the adsorption of micropollutants is better than the adsorption of NOM in natural groundwater.

Figure 4 Simulation of the adsorption of EBC (Equivalent Background Compound) (\square g DOC/L) onto ACFC in the presence of micropollutants

Table 8 : Modeling of adsorption isotherms in natural waters

		Parameters				E (%)
Matrix	C ₀ EBC ($\mu\text{g}\cdot\text{L}^{-1}$)	(units with q_e in $\mu\text{g}\cdot\text{g}^{-1}$ and C_e in $\mu\text{g}\cdot\text{L}^{-1}$)				
		q_m	b	n		
Caffeine	UPW		$2.6\cdot 10^3$	5.3	1.8	39.7
EBC	GW	19.5	$1.6\cdot 10^3$	0.6	1.5	
Acetaminophen	UPW		$4.2\cdot 10^3$	4.5	1.1	28.9
EBC	GW	19.9	$3.8\cdot 10^3$	0.2	1.1	
Diclofenac	UPW		$2.9\cdot 10^3$	0.4	0.9	34.5
EBC	GW	20.2	$1.6\cdot 10^3$	1.2	3.2	
Carbamazepine	UPW		$2.6\cdot 10^3$	0.6	1.3	14.3
EBC	GW	20.3	$1.5\cdot 10^3$	0.4	1.4	
Ibuprofen	UPW		$4.9\cdot 10^3$	0.2	1.4	18.3
EBC	GW	24.6	$3.8\cdot 10^3$	0.1	0.8	
Mecoprop	UPW		$4.4\cdot 10^3$	0.6	1.0	40.4
EBC	GW	20.1	$3.3\cdot 10^3$	0.1	1.9	
Benzotriazole	UPW		$5.4\cdot 10^3$	0.8	1.4	45.1
EBC	GW	19.9	$1.9\cdot 10^3$	0.1	0.9	
Bisphenol A	UPW		$8.9\cdot 10^3$	0.2	2.0	40.4
EBC	GW	20.0	$3.3\cdot 10^3$	0.1	1.9	

4 Conclusion

The adsorption of eight micropollutants onto activated carbon fiber cloth (ACFC) was studied in batch reactors (kinetics and isotherm equilibria) within three aqueous matrices: ultrapure, ground waters and diluted (1/2) groundwater. Experimental data of adsorption were generated for 8 pharmaceutical residues in mixture at low concentrations (between 100 ng/L to 10 $\mu\text{g}/\text{L}$). We have to note the

adsorption of such pharmaceutical residues. The impacts of NOM were enlightened. Indeed, in batch reactors, large detrimental influences of NOM were shown on adsorption capacities. The reduction higher than 75 % in natural water, containing 2.9 mgDOC.L⁻¹ approximately, was found in comparison to ultrapure water). The kinetics were modeled with HSDM and IAST model. The mass transfer coefficients and the diffusion coefficients were determined. They are found respectively in the order of $K_f = 10^{-2}$ and $10^{-9} < D_s < 10^{-10}$. The Biot numbers had shown that the limiting mechanisms (external transfer and/or inner diffusion in the pore) were highly dependent on the nature of the target compound and, most often, affected by the presence of NOM.
