ABSTRACT.

Reactions, in hydro-thermal conditions, between a lanthanide chloride and the sodium salt of 2-carboxyphenylboronic acid lead to a series of lanthanide-based complexes with general chemical formula $[\text{Ln}_2(\text{C}_7\text{H}_5\text{O}_2)_4(\text{C}_7\text{O}_4\text{H}_6\text{B})_2 \cdot 4\text{H}_2\text{O}]$ with $\text{Ln} = \text{Eu-Dy}$. During the synthetic process, 2-carboxyphenylboronate ligand decomposes leading to benzoate ($\text{C}_7\text{H}_5\text{O}_2$) and bis(hydroxy)benzoxaborolone ($\text{C}_7\text{O}_2\text{H}_6\text{B}$). Crystal structure was solved on the basis of the Tb-derivative. It crystallizes in the triclinic system, space group $P\bar{1}$ (n°2) with $a = 9.3329(13) \text{ \AA}$, $b = 16.012(2) \text{ \AA}$, $c = 16.212(2) \text{ \AA}$, $\alpha = 107.789(5)^\circ$, $\beta = 90.226(5)^\circ$, $\gamma = 97.585(5)^\circ$, $V = 2284.16(52) \text{ \AA}^3$ and $Z = 2$. Crystal structure can be described on the basis of di-lanthanides complexes surrounded by the ligands. Compounds that constitute these series are thermally stable up to 190°C . Solid-state luminescent properties have been studied in details. Dy-derivative magnetic properties have also been explored. It presents a Single Molecule Magnet behavior. Single crystals of the sodium salt of 2-carboxyphenylboronic acid with chemical formula $[\text{Na}(\text{C}_7\text{O}_4\text{H}_6\text{B})(\text{H}_2\text{O})]_\infty$ have also been obtained during this study. This compound crystallizes in the orthorhombic system, space group $P2_12_12_1$ (n°19) with $a = 4.5881(13) \text{ \AA}$, $b = 6.5905(16) \text{ \AA}$, $c = 29.644(8) \text{ \AA}$, $V = 897.0(4) \text{ \AA}^3$ and $Z = 4$. Crystal structure is 2D and can be described as zig-zag chains of sodium 2-carboxyphenylboronate bound to each other by coordination water molecules.

INTRODUCTION.

For more than a decade, luminescent lanthanide-based coordination polymers have attracted a growing interest because of their various potential fields of technological applications.^[1-13] Our group is involved in that field for almost twenty years^[14] and the quest for new ligands leading to new lanthanide-based coordination polymers that exhibits original photo-physical properties constitutes a continuous concern.^[15-17] Therefore, some years ago, we have decided to explore carboxy-boronic ligands because boronate function can act as a tri-dentate function.^[18] Moreover, carboxy-boronic acids present both Lewis and Brönsted acid characters (Scheme 1) and, up to date, only a few examples of crystal structures of coordination polymers based on boronates have been reported. Indeed, most of the reported coordination polymers crystal structures involve alkaline earth metal ions^[18-21] or transition metal ions.^[22]

Scheme 1. Illustration of the Lewis and Brönsted acidic character of 4-carboxyphenylboronic acid (Hcpb).

Our work, along this line, has led to the first lanthanide-based coordination polymers with 4-carboxyphenylboronic acid with interesting structural and luminescent properties.^[23-24] In 2017, Yang Z.-R. *et al.* reported an Eu-based coordination polymer with 5-borono-isophthalic acid. This compound exhibits excellent selective ratiometric fluorescence detection of fluoride ions.^[25] On the basis of these results we have decided to explore the synthesis of lanthanide-based coordination polymers based on 2-carboxyphenylboronic acid (Scheme 2).

Scheme 2. Schematic representation of 2-carboxyphenylboronic acid hereafter referenced as o-cpbH.

EXPERIMENTAL SECTION.

Synthesis.

Lanthanide oxides (99.99%) have been purchased from Ampere Industry and used without further purification. Lanthanide chlorides have been prepared according to established procedures.^[26]

Synthesis of (Na(o-cpb) H₂O)

2-carboxyphenylboronic acid (H(o-cpb)) (97 %) has been purchased from TCI and used without further purification. Microcrystalline powder of its sodium salt (Na(o-cpb) H₂O) has been prepared on the basis of a previously described procedure:^[24] an aqueous solution of sodium hydroxide (7.10^{-3} mol in 10 mL of water) was added dropwise to a suspension in deionized water of the commercial acid (6.10^{-3} mol in 10 mL of water). The obtained clear solution was evaporated to dryness. The obtained solid was then dissolved in ethanol and precipitated again by addition of diethylether as a gel. The gel was filtered and dissolved in water and the obtained clear solution evaporated to dryness. Hygroscopic microcrystalline powder that was finally obtained was kept under dry atmosphere. Yield was close to 100%. C₇H₈BO₅Na (MW = 205.8 g.mol⁻¹) Analysis: (calc.) found: C (40.8%) 40.8%; H (3.9%) 4.0%; B (5.2%) 5.3%; O (38.9%) 38.7%; Na (11.2%) 11.2%.

Single-crystals of Na(o-cpb) H₂O have been obtained by slow evaporation of an aqueous solution of the salt, at room-temperature. Crystal and final structure refinement data are listed in Table 1. Iso-structurality of the microcrystalline powder and of the single-crystal

has been assumed on the basis of experimental and simulated from the crystal structure X-ray powder diffraction diagrams (Figure S1). Crystal structure, thermal analysis and UV-vis spectrum are depicted in supporting information (Figures S2-S4).

Synthesis of $[\text{Ln}_2(\text{C}_7\text{H}_5\text{O}_2)_4(\text{C}_7\text{O}_4\text{H}_6\text{B})_2 \cdot 4\text{H}_2\text{O}]$ with Ln = Eu-Dy

Iso-structural coordination polymers with general chemical formula $[\text{Ln}_2(\text{C}_7\text{H}_5\text{O}_2)_4(\text{C}_7\text{O}_4\text{H}_6\text{B})_2 \cdot 4\text{H}_2\text{O}]$ with Ln = Eu-Dy have been obtained by sealing a mixture of a lanthanide chloride (0.25 mmol), of the sodium salt of 2-carboxyphenylboronic acid (0.5 mmol) and of deionized water (4-10 mL) in a 20 mL Teflon-line vessel. The mixture was heated at 110°C for 3 days and slowly cooled-down to room-temperature (5 °C.h⁻¹). Colorless hexagonal plate-like single-crystals suitable for single-crystal X-ray diffraction were obtained (Figure 1). Their size depended of the water volume. As expected, the less concentrated the solution was, the bigger the single-crystals were. Yields of the synthesis were very low (a few single crystal per batch). Therefore, iso-structurality of the compounds that constitute this series was assumed on the basis of cell parameters measurements (Table S1). Crystal structure was solved on the basis of the Tb-containing derivative. Crystal and final structure refinement data are listed in Table 1. Elemental analyses are gathered in Table S2.

Figure 1. Pictures under UV light (top) and day light (bottom) of single-crystals of $[\text{Tb}_2(\text{C}_7\text{H}_5\text{O}_2)_4(\text{C}_7\text{O}_4\text{H}_6\text{B})_2 \cdot 4\text{H}_2\text{O}]$ versus the water volume used during the synthesis. White bars represent 200 μm .

X-ray diffraction.

Powder X-ray diffraction diagram was collected on a Panalytical X'pert Pro equipped with an X'Celerator (45 kV, 40 mA for Cu $K\alpha$ ($\lambda = 1.542 \text{ \AA}$) in θ/θ mode). Simulated diffractogram was produced with Powdercell and WinPLOTR software programs.^[27-29]

Single-crystals were mounted on a Bruker D8 Venture diffractometer. Crystal data collection were performed at 150 K with Mo $K\alpha$ radiation ($\lambda = 0.70713 \text{ \AA}$). Crystal structures were solved, using SIR 97,^[30] by direct methods. They were refined, using SHELX97^[31] with the aid of WINGX program.^[32-33] All non-hydrogen atoms were refined anisotropically. Hydrogen atoms that have been located were located at ideal positions. Absorption corrections were performed using the facilities of WINGX program.^[34] Full details of the crystal structures have been deposited with the Cambridge Crystallographic Data Centers under the depositary numbers CCDC-1943082 for Na(o-cpb) H_2O and CCDC-1909669 for $[\text{Tb}_2(\text{C}_7\text{H}_5\text{O}_2)_4(\text{C}_7\text{O}_4\text{H}_6\text{B})_2 \cdot 4\text{H}_2\text{O}]$. It can be noticed that there is some residual electronic density in the vicinity of the molecular skeleton. It can be related to the sizeable mosaicity of the single-crystals. Despite great efforts we did not succeed in growing single-crystals of better quality.

Thermal analyses.

Thermal analyses of Na(o-cpb) H₂O and [Tb₂(C₇H₅O₂)₄(C₇O₄H₆B)₂·4H₂O] have both been performed using a Perkin Elmer Pyris Diamond TGA/TDA, between 20°C and 950°C in platinum crucibles under N₂ atmosphere.

Optical measurements.

Solid-state emission and excitation spectra have been measured on a Horiba Jobin-Yvon Fluorolog III fluorescence spectrometer equipped with a Xe lamp 450 W and a UV-Vis photomultiplier (Hamamatsu R928, sensitivity 190-860 nm) and an IR-photodiode cooled by liquid nitrogen (InGaAs, sensitivity 800-1600 nm). Most of the luminescence spectra were recorded at room-temperature. The emission/excitation spectra recordings were realized on powder samples introduced in cylindrical quartz cells of 0.7 cm diameter and 2.4 cm height, which were placed directly inside the integrating sphere, or on powder samples

pasted on copper plates with silver glue. The phosphorescence of the Gd-based microcrystalline powders, introduced in quartz capillary tubes, has been measured in a cold finger at 77 K (Dewar + liquid nitrogen). Quantum yield measurements were performed using a Jobin-Yvon integrating sphere ($\Phi = (E_c - E_a)/(L_a - L_c)$) with E_c being the integrated emission spectrum of the sample, E_a the integrated “blank” emission spectrum, L_a the “blank” absorption and L_c the sample absorption at the excitation wavelength). Integrated sphere has been calibrated using europium tris-dipiconilate in the solid-state^[35] and cesium dipiconilate in the liquid-sate.^[36] Luminescence decays ($\tau > 10 \mu s$) have also been measured at room-temperature using this apparatus with a Xenon flash lamp (phosphorescence mode). Lifetimes are averages of two or three independent determinations. Appropriate filters were used to remove the residual excitation laser light, the Rayleigh scattered light and associated harmonics from spectra. All spectra were corrected for the instrumental response function.

Absorption spectra were recorded with a Perkin Elmer Lambda 650 UV/vis spectrometer equipped with a 60 mm integrating sphere at room-temperature.

Magnetic measurements

A Quantum Design MPMS SQUID magnetometer has been used to perform magnetic measurements on powder pressed into Teflon pellet in order to avoid in-field orientation of the crystallites. All measurements were corrected for the diamagnetic contribution of the sample as calculated from Pascal’s constants.

RESULTS AND DISCUSSION

Crystal structure of $[\text{Ln}_2(\text{C}_7\text{H}_5\text{O}_2)_4(\text{C}_7\text{O}_4\text{H}_6\text{B})_2 \cdot 4\text{H}_2\text{O}]$ with $\text{Ln} = \text{Eu-Dy}$.

Reactions in hydrothermal conditions of a lanthanide chloride ($\text{Ln} = \text{Eu-Dy}$) and the sodium salt of 2-carboxyphenylboronic acid lead to a family of iso-structural lanthanide-based complexes (Scheme 3).

Scheme 3. Schematic representation of the di-nuclear complex $[\text{Tb}_2(\text{C}_7\text{H}_5\text{O}_2)_4(\text{C}_7\text{O}_4\text{H}_6\text{B})_2 \cdot 4\text{H}_2\text{O}]$.

The crystal structure has been solved on the basis of the Tb-derivative. It can be described on the basis of di-lanthanide complexes. During the synthesis, 2-carboxyphenylboronate ligand decomposed and led to benzoate in one hand and bis(hydroxy)benzoxaborolone in the other hand.^[18] Thermal analyses of $[\text{Tb}_2(\text{C}_7\text{H}_5\text{O}_2)_4(\text{C}_7\text{O}_4\text{H}_6\text{B})_2 \cdot 4\text{H}_2\text{O}]$ (Figure S5) are in agreement with the crystal structure. Indeed the dehydration of the $-\text{B}(\text{OH})_2$ groups is also observed leading to a total departure of 6 water molecules per formula unit (9%).

There is only one crystallographically independent Tb^{3+} ion in the crystal structure. It is eight coordinated (Figure 2) by two oxygen atoms from a bidentate benzoate, two oxygen

atoms from two bridging benzoate, two oxygen atoms from a bis(hydroxy)benzoxaborolone molecule and two oxygen atoms from two coordination water molecules that form a slightly distorted dodecahedron. The two lanthanide ions that belong to the same di-lanthanide complex are linked by two bridging carboxylate functions from two benzoate ligands and by intramolecular hydrogen bonds that involve coordination water molecules (Figure 2). Intra-molecular intermetallic distance is 4.8688(7) Å. The complex is globally planar and elongated along the *c*-axis (Figure 2). The molecular stacking is insured via a complex hydrogen-bonds network that involve -OH groups from the boronic function, the oxygen atom of the ketone function, oxygen atoms from the carboxylate functions and coordination water molecules.

Figure 2. Top: projection views along the *a*-axis (left) and the *b*-axis (right) of a complex $[\text{Tb}_2(\text{C}_7\text{H}_5\text{O}_2)_4(\text{C}_7\text{O}_4\text{H}_6\text{B})_2 \cdot 4\text{H}_2\text{O}]$. Bottom: Projection view along the *b*-axis of an extended unit cell of $[\text{Tb}_2(\text{C}_7\text{H}_5\text{O}_2)_4(\text{C}_7\text{O}_4\text{H}_6\text{B})_2 \cdot 4\text{H}_2\text{O}]$. Most relevant hydrogen-bonds are symbolized by yellow broken line

Luminescent properties of $[\text{Ln}_2(\text{C}_7\text{H}_5\text{O}_2)_4(\text{C}_7\text{O}_4\text{H}_6\text{B})_2 \cdot 4\text{H}_2\text{O}]$ with Ln = Eu-Dy.

Energies of the lowest singlet and triplet excited states of the ligands have been estimated on the basis of the excitation and emission spectra of the Gd-derivative recorded at 77 K. They have been estimated by referring to the wavelength of the excitation edge ($E_{1\pi-1\pi^*} = 335 \text{ nm} = 29850 \text{ cm}^{-1}$) and of the shortest wavelength of the phosphorescent band of the ligands ($E_{1\pi-3\pi^*} = 370 \text{ nm} = 27000 \text{ cm}^{-1}$), respectively (Figure 3).³⁷⁻³⁹ Empirical Reinhoudt's rules⁴⁰⁻⁴¹ predict that these values are not supposed to favor efficient intercrossing system process. Indeed, difference between these two excited states ($\Delta E = E_{1\pi^*} - E_{3\pi^*} = 2850 \text{ cm}^{-1}$) is smaller than 5000 cm^{-1} . However, it must be noticed that in this complex there are two distinct ligands. This makes questionable a precise experimental assignation of the excitation and emission peaks.

Excitation spectrum of the Gd-based complex presents a maximum centered at 326 nm that is also observed in excitation spectra of the Tb- and Dy-derivatives (Figures 4 and 5). This strongly suggests that one out of the two ligands acts as an efficient antenna toward these two lanthanide ions.⁴² In the following, it has been assumed that this excitation peak is related to bis(hydroxy)benzoxaborolone ligand because benzoate absorption peak is expected at lower wavelength ($< 300 \text{ nm}$).⁴³⁻⁴⁴

Figure 3. Solid state excitation and emission spectra of $[\text{Gd}_2(\text{C}_7\text{H}_5\text{O}_2)_4(\text{C}_7\text{O}_4\text{H}_6\text{B})_2 \cdot 4\text{H}_2\text{O}]$ recorded at 77 K. Luminescence lifetime at 77 K is 3.1(1) ms under excitation at 326 nm.

Emission spectra of $[\text{Tb}_2(\text{C}_7\text{H}_5\text{O}_2)_4(\text{C}_7\text{O}_4\text{H}_6\text{B})_2 \cdot 4\text{H}_2\text{O}]$ have been recorded under two excitation wavelengths (Figure 4). Emission spectrum measured by irradiation of the ligand ($\lambda_{\text{exc}} = 326 \text{ nm}$) is much more intense than the one obtained by direct excitation of the lanthanide ion ($\lambda_{\text{exc}} = 378.5 \text{ nm}$; ${}^7\text{F}_6 \rightarrow {}^5\text{G}_6$). Emission spectrum shows all the characteristic emission peaks of Tb^{3+} ion (${}^5\text{D}_4 \rightarrow {}^7\text{F}_{6-0}$) and is dominated by the ${}^5\text{D}_4 \rightarrow {}^7\text{F}_5$ transition (543.5 nm) that induces green luminescence. Overall quantum yield ($Q_{\text{Tb}}^{\text{Ligand}}$) and luminescence lifetime (τ_{obs}) have been measured: $Q_{\text{Tb}}^{\text{Ligand}} = 79(6) \%$ and $\tau_{\text{obs}} = 0.84(1) \text{ ms}$ ($\lambda_{\text{ex}} = 326 \text{ nm}$ or 378.5 nm ; room-temperature). This sizeable overall quantum yield is in agreement with empirical Latva's rules⁴⁵⁻⁴⁶ that predict efficient Ligand-to- Tb^{3+} energy transfer without significant back-transfers ($\Delta E({}^3\pi^* - {}^5\text{D}_4) = 27000 - 20500 = 6500 \text{ cm}^{-1}$). It also suggests that part of the energy absorbed by the ligand is directly transferred from ligand first excited singlet state to Tb^{3+} emitting levels.

Figure 4. Solid state excitation and emission spectra of $[\text{Tb}_2(\text{C}_7\text{H}_5\text{O}_2)_4(\text{C}_7\text{O}_4\text{H}_6\text{B})_2 \cdot 4\text{H}_2\text{O}]$ at room-temperature. Luminescence lifetime is 0.84(1) ms for both excitation wavelengths.

Excitation spectrum of the Dy-based complex also exhibits a broad excitation peak centered at 326 nm which suggests that antenna effect is efficient also for this complex. Emission spectra have been recorded in both the visible and the IR regions (Figure 5). In the visible domain it exhibits the characteristic transitions of the Dy^{3+} ions: $^4\text{F}_{9/2} \rightarrow ^6\text{H}_{15/2-9/2}$. It is dominated by the $^4\text{F}_{9/2} \rightarrow ^6\text{H}_{13/2}$ transition at 574 nm which produces a yellowish emission. In the IR domain emission spectrum exhibits characteristic transitions of the Dy^{3+} ion: $^4\text{F}_{9/2} \rightarrow ^6\text{H}_{7/2-5/2}$ and $^4\text{F}_{9/2} \rightarrow ^6\text{F}_{9/2-5/2}$. These transitions are of weak intensities. This could be related to the weak energy gap between the luminescent Dy^{3+} energy state ($^4\text{F}_{9/2}$) and the receiving level that favors non-radiative de-excitation.³⁹ These weak intensities are confirmed by low quality (low signal/noise ratio) of the excitation spectrum recorded at 836 nm (Figure 5 bottom).

Figure 5. Solid state excitation and emission spectra of [Dy₂(C₇H₅O₂)₄(C₇O₄H₆B)₂·4H₂O] at room-temperature. Luminescence has been observed in both visible (top) and IR (bottom) domains.

Solid-state excitation and emission spectra of [Eu₂(C₇H₅O₂)₄(C₇O₄H₆B)₂·4H₂O] have been recorded (Figure 6). Excitation spectrum doesn't present the characteristic band attributed to the ligand (326 nm) and emission spectrum under direct excitation of the Eu³⁺ ion (394 nm; $^7F_0 \rightarrow ^5L_6$) is much more intense than emission spectrum recorded under ligand excitation. Emission spectrum exhibits all the characteristic transition of Eu³⁺ ion:

$^5D_0 \rightarrow ^7F_{0-6}$. It is dominated by the $^5D_0 \rightarrow ^7F_2$ transition (616 nm) that produces a red luminescence.

Figure 6. Solid state excitation and emission spectra of $[\text{Eu}_2(\text{C}_7\text{H}_5\text{O}_2)_4(\text{C}_7\text{O}_4\text{H}_6\text{B})_2 \cdot 4\text{H}_2\text{O}]$ at room-temperature. Luminescence lifetime is 0.28(1) ms for both excitation wavelengths.

Overall quantum yield ($Q_{\text{Eu}}^{\text{Ligand}}$) and intrinsic quantum yields ($Q_{\text{Eu}}^{\text{Eu}}$) have been measured: $Q_{\text{Eu}}^{\text{Ligand}} = 0.62(2) \%$ and $Q_{\text{Eu}}^{\text{Eu}} = 20.9(6) \%$. Sensitization efficiency ($\eta_{\text{sens}} = 3.0 \%$) has been calculated according to relationship:³⁹

$$Q_{\text{Eu}}^{\text{Ligand}} = \eta_{\text{sens}} \times Q_{\text{Eu}}^{\text{Eu}} \quad (1)$$

This low value confirms that antenna effect is inefficient for the Eu-based complex. This can be related to a photo-induced electron transfer (PET) mechanism that occurs when a donating ion is in the vicinity of an easily reducible lanthanide ion such as Eu^{3+} .^{38, 47-50} This strongly supports the assumption that bis(hydroxy)benzoxaborolone is responsible for the antenna effect observed for the Tb- and Dy-derivatives because benzoate ligand can't be involved in a PET mechanism.

Magnetic properties of $[\text{Dy}_2(\text{C}_7\text{H}_5\text{O}_2)_4(\text{C}_7\text{O}_4\text{H}_6\text{B})_2 \cdot 4\text{H}_2\text{O}]$

Lanthanide-based molecules are good candidate to observe Single-Molecule Magnet (SMM) behavior.⁵¹ Such behavior is seen when an anisotropic magnetic molecule is magnetically isolated from its neighbors. In that case, it can present magnetic slow relaxation and thus behave as a magnet at a molecular level.

In an appropriate coordination environment the Dy^{III} ion can be extremely anisotropic ($g_x = 0$, $g_y = 0$, $g_z = 20$ if a $S = 1/2$ ground state is considered) and most of Ln-SMMs are based on this ion. One of the strategies to obtain Dy-SMM is to synthesize Dy^{III} dimers⁵²⁻⁵⁴ where Dy-Dy intramolecular magnetic interaction can influence the SMM properties.⁵⁵⁻⁵⁹

$[\text{Dy}_2(\text{C}_7\text{H}_5\text{O}_2)_4(\text{C}_7\text{O}_4\text{H}_6\text{B})_2 \cdot 4\text{H}_2\text{O}]$ is a dimer in which Dy^{III} ions are eight coordinated by oxygen ligands. Continuous Shape measurement (CShM)⁶⁰⁻⁶¹ shows that the coordination polyhedron of Dy1 and Dy2 are highly similar and are triangular dodecahedron (D_{2d} site symmetry, CShM = 2.099 and 2.102 for Tb1 and Tb2, respectively, Table S3). This coordination polyhedron is not particularly suitable for the observation of SMM behavior.⁶²⁻⁶⁶ However, one can see that the height oxygens are very different on the electrostatic point of view. Indeed, the most charged oxygens atoms are above, below and in the plane of the $\text{B}(\text{OH})_2$ clamp. This means that the Dy^{III} feels an electrostatic field that is axial or equatorial, with almost no transverse component (Figure 7). If the axial electrostatic field is strong enough a SMM behavior could be expected because it stabilizes the Dy^{III} highly anisotropic magnetic ground state ($M_J = \pm 15/2$).

Figure 7. Representation of the two dimers found in $[\text{Dy}_2(\text{C}_7\text{H}_5\text{O}_2)_4(\text{C}_7\text{O}_4\text{H}_6\text{B})_2 \cdot 4\text{H}_2\text{O}]$ with Dy coordination polyhedron and Dy-Dy distances highlighted.

Static magnetic measurements have been performed and room-temperature $\chi_{\text{M}}T_{(300\text{K})} = 28.29 \text{ emu.K.mol}^{-1}$, close to the expected value of $28.34 \text{ emu.K.mol}^{-1}$ for two isolated Dy^{III} ions ($J = 5/2$, $g_{\text{j}} = 4/3$) (Figure S6). As the temperature is lowered, a continuous decrease of $\chi_{\text{M}}T$ is observed that is a consequence of the depopulation of the Dy^{III} Stark sub-levels. The Dy-Dy magnetic coupling is expected to be very weak because i) carboxylate clamps in η_2 coordination mode are known to be inefficient in transmitting magnetic exchange interactions ii) Dy1-Dy1 and Dy2-Dy2 distances are $4.84 \text{ \AA}$, too long to observe any significant intramolecular magnetic coupling.

Dynamic magnetic measurements show not out-of phase (χ_{M}'') magnetic relaxation in absence of a magnetic dc field. However, as a field is applied a slow relaxation is observed that is optimized for $H_{\text{dc}} = 1200 \text{ Oe}$ (Figure S7). With this field, temperature dependent dynamic measurements are performed and clear magnetic slow relaxation is observed between 1.8 and 10 K (Figure 8 and S8). The relaxation times are extracted considering and modified Debye law ⁶⁷ (Table S4) and an Arrhenius plot is reported in Figure 8. In the high temperature regime, an Orbach magnetic relaxation can be considered and the relaxation time

is $\tau = \tau_0 \exp(U_{\text{eff}}/k_B T)$ where τ_0 is the characteristic relaxation time, U_{eff} is the activation energy required for the spin reversal and k_B is the Boltzmann constant. For $[\text{Dy}_2(\text{C}_7\text{H}_5\text{O}_2)_4(\text{C}_7\text{O}_4\text{H}_6\text{B})_2 \cdot 4\text{H}_2\text{O}]$, $\tau_0 = 6.82 \times 10^{-7}$ s and $U_{\text{eff}} = 41.7$ K (28.9 cm^{-1}), values that compares well with what observed in the literature.⁵² At low temperature the relaxation times saturates around 0.1 s as a consequence of the onset of a temperature independent relaxation. It can be noted that no reliable fitting considering Raman relaxation or its combination with Orbach and/or quantum tunneling regimes could be obtained.

Figure 8. Frequency (left) and temperature dependence (right) of the out-of phase magnetic susceptibility χ_M'' of $[\text{Dy}_2(\text{C}_7\text{H}_5\text{O}_2)_4(\text{C}_7\text{O}_4\text{H}_6\text{B})_2 \cdot 4\text{H}_2\text{O}]$ measured with a static magnetic field $H_{\text{dc}} = 1200$ Oe.

On $[\text{Dy}_2(\text{C}_7\text{H}_5\text{O}_2)_4(\text{C}_7\text{O}_4\text{H}_6\text{B})_2 \cdot 4\text{H}_2\text{O}]$, the distribution of the relaxation times is moderate (Figure 9, Table S5) with α that ranges between $\alpha = 0.2$ and 0.01 (the lower is α , the less distributed is the magnetic relaxation, with $0 < \alpha < 1$). Moreover the relaxing fraction (RF), calculated as $\text{RF} = 1 - (\chi_S/\chi_T)$ is quite high (χ_S and χ_T are the adiabatic and isothermal susceptibility respectively). $\text{RF}_{(2\text{K})} = 80\%$ and $\text{RF}_{(9\text{K})} = 62\%$. This means that most of the sample relaxes slowly (high RF), with almost one single relaxation time (low α).

Figure 9. (left) Arrhenius plot of the relaxation times measured on $[\text{Dy}_2(\text{C}_7\text{H}_5\text{O}_2)_4(\text{C}_7\text{O}_4\text{H}_6\text{B})_2 \cdot 4\text{H}_2\text{O}]$ with best fit of the linear region (red line) and extrapolation of the low temperature region (black line). (right) Cole-Cole plot of the magnetic susceptibilities of $[\text{Dy}_2(\text{C}_7\text{H}_5\text{O}_2)_4(\text{C}_7\text{O}_4\text{H}_6\text{B})_2 \cdot 4\text{H}_2\text{O}]$ with best fits as black lines and ideal relaxation curve ($\alpha = 0$, RF = 100%) as red dotted line.

CONCLUSION AND OUTLOOK.

In this paper we report two new crystal structures of compounds based on boronic derivatives. Lanthanide based-complexes that are described were unexpected. However they present interesting luminescent and magnetic properties. These results evidence that boronic ligands are good candidates for lanthanide coordination chemistry.
